Orocopia Valley Groundwater Basin (No. 7-31): This basin covers approximately 150 square miles (96,000 acres) northeast of the Salton Sea entirely within Riverside County. It is bounded by impermeable rocks of the Cottonwood and Eagle Mountains on the north and the Orocopia and Chocolate Mountains on the south. The basin is bounded by a section of the San Andreas fault zone and semi-permeable rocks of the Mecca Hills to the west and by a bedrock constriction to the east. The western portion of the valley drains westward toward the Salton Sea, but the eastern part drains eastward into Hayfield (Dry) Lake and Chuckwalla Valley. Average annual precipitation within the Orocopia Valley ranges to 4 inches.

The water-bearing hydrogeologic units within the basin consist of alluvial and lake deposits up to 4,400 feet thick near Hayfield Lake where alluvial materials have deposited from surrounding mountains. Data shows groundwater levels ranging from about 480-500 feet below ground surface. Natural recharge is thought to occur from subsurface inflow and infiltration of runoff from the surrounding mountains and rainfall to the valley floor. MWD operates an artificial groundwater recharge site in the Hayfield Lake area near the Julian Hinds Pumping Station for the Colorado River Aqueduct. (Under the Hayfield Groundwater Storage Program, Colorado River Aqueduct water is stored for future withdrawal and delivery. As of 2003, MWD reports 73,300 AF in storage.)

In 1975, the DWR reported total storage capacity of the basin at 1,500,000 AF. A slightly later study estimated a storage capacity of about 6,250,000 AF. In 1980, the amount of groundwater in storage was reported to have been about 4,300,000 AF. Subsurface inflow from adjacent basins is estimated at about 1,600 AFY and natural recharge to the basin can be as high as 4,700 AFY. Subsurface outflow from the basin can be as high as 6,200 AFY. Inflow is considered generally equal to outflow for this basin.

Mineral analyses indicate that the groundwater in the basin ranges from sodium bicarbonate to sodium sulfate in character. Near Hayfield Lake, TDS content ranges from 254 to 665 mg/L, but most wells sampled measured at less than 300 mg/L. Data from 2000 indicate that fluoride, colorants, radon and uranium concentrations in some wells exceed drinking water standards. Active monitoring data for Title 22 water quality was reported for one well in the basin. In the eastern basin, the Hayfield Lake area near the Julian Hinds Pumping Station, is managed by MWD as a conjunctive use project site. No other public or private water agencies are noted as utilizing the basin.

Chocolate Valley Groundwater Basin (No. 7-32): This basin covers approximately 203 square miles and is bounded by the Chocolate Mountains to the south and southeast, and the Orocopia and Chuckwalla Mountains to the north. The Salton Sea forms its western boundary. Much of the southeast portion of the valley lies within the Chocolate Mountain Aerial Gunnery Range. Annual average precipitation ranges from 3-5 inches.

Surface runoff from the surrounding mountains drains to the Salton Sea via Salton Creek. Water depth for the basin was found to range between 89-99 feet below the ground surface in the 1970s. Recharge to the basin is derived chiefly from the infiltration of runoff through alluvial deposits at the base of the surrounding mountains. Groundwater moves southwest beneath Salton Creek and discharges to the Salton Sea to the west. Natural recharge to the basin is estimated at 200 AFY. The amount of water in the basin is unknown, but the total storage capacity is estimated at 1,000,000 AF.

Prominent minerals in the basin's water include sodium, chloride and sulfate. The water's quality is impaired by elevated levels of fluoride (0.6-60.0 mg/L), boron (0.08-15.8 mg/L) and TDS (460-24,500 mg/L; 3,000 mg/L average). There are no known public wells or water agencies associated with this groundwater basin.

Palo Verde Mesa Groundwater Basin (No. 7-39): This basin covers approximately 353 square miles in the Parker Valley region of eastern Riverside County. The Big Maria and Little Maria Mountains bound the basin to the north, the McCoy and Mule Mountains to the west, the Palo Verde Mesa to the east and the Palo Verde

Mountains to the south. The valley is drained by McCoy Wash, which empties into the Colorado River to the southeast. Average annual precipitation ranges to 6 inches.

Recharge to the basin is assumed to be chiefly from percolation of runoff from the surrounding mountains, with percolation of precipitation on the valley floor and subsurface inflow possibly providing additional sources of recharge. Natural recharge to the basin is estimated at about 800 AFY, plus 400 AFY of recharge occurring from underflow from Chuckwalla Valley. The total storage capacity of the basin is estimated at 6,840,000 AF; the amount currently in storage is unknown.

Analysis of water from 11 public supply wells in the basin show TDS content ranges from 90-1,790 mg/L, with an average of 1,089 mg/L. The groundwater tends to be calcium-sodium chloride or calcium-sodium sulfate in nature. The water's quality is impaired by elevated levels of arsenic, selenium, fluoride, chloride, boron, sulfate and TDS concentrations. (No concentration values provided.) There are 20 USGS wells for groundwater monitoring and 13 known wells for water supply (presumably potable) use in this groundwater basin.

4. South Coast Hydrologic Region – Groundwater Basins

DWR Bulletin 118 reports that the South Coast Hydrologic Region covers approximately 6.78 million acres (10,600 square miles) of the Southern California watershed that drains to the Pacific Ocean. It is bounded on the west by the Pacific Ocean and the watershed divides near the Ventura-Santa Barbara County line. The northern boundary is formed by the Transverse Ranges of the San Gabriel and San Bernardino mountains. The eastern boundary lies along the crest of the San Jacinto Mountains and low-lying hills of the Peninsular Range that abut the Colorado River Hydrologic Region and the southern boundary is Mexico. The region spans all of Orange County, most of San Diego and Los Angeles Counties, parts of Riverside, San Bernardino and Ventura Counties. It also includes a small amount of Kern and Santa Barbara Counties. The Santa Ana River subregion, regulated by the Santa Ana Regional Water Quality Control Board (RWQCB), is denoted by basins beginning with an "8." Likewise, the San Diego subregion, denoted by a "9," is regulated by the San Diego RWQCB. The Los Angeles subregion is denoted by a "4."

Per the 2000 U.S. Census, roughly 17 million people, nearly half the state's population, live within the South Coast Hydrologic Region. The region's surface area, however, only covers roughly 7% of the state. Thus, this region has the highest population density of any of the state's hydrologic regions. Overall, 56 delineated groundwater basins underlie about 2.27 million acres (3,530 square miles), or about 33%, of the South Coast Hydrologic Region. Of these, 21 are in subregion 4 (Los Angeles), eight are in subregion 8 (Santa Ana) and 27 are in subregion 9 (San Diego). Groundwater basins underlie 979,000 acres (1,520 square miles), or about 54%, of the Santa Ana subregion, including the Upper Santa Ana Valley Groundwater Basin, which is further divided into nine subbasins. The San Diego subregion overlies 27 groundwater basins and encompasses most of San Diego County, with additional parts of Orange and Riverside Counties. Groundwater basins underlie about 277,000 acres (433 square miles) or about 11% of the surface of the San Diego subregion.

With its long history of settlement, groundwater has been used in the South Coast region for well over 100 years. High demand and use of groundwater in Southern California has given rise to many disputes over management and pumping rights, with the resolution of these cases playing a large role in the establishment and clarification of water rights law in California. Raymond Groundwater Basin, located in this hydrologic region, was the first adjudicated basin in the state. Of the 16 adjudicated basins in California, 11 are in the South Coast region.

Groundwater provides about 23% of water demand in normal years and about 29% in drought years. Groundwater is found in unconfined alluvial aquifers in most of the basins of the San Diego subregion and the inland basins of the Santa Ana and Los Angeles subregions. In some larger basins, typified by those underlying

the coastal plain, groundwater occurs in multiple aquifers separated by geological barriers that create confined groundwater conditions. Basins range in depth from tens or hundreds of feet in smaller basins, to thousands of feet in larger basins. The thickness of aquifers varies from tens to hundreds of feet. Well yields vary depending on aquifer characteristics, well location, size and use. Some aquifers are capable of yielding thousands of gallons per minute to municipal wells.

Conjunctive use of surface and groundwater is a long-standing practice in the region. At present, much of the potable water used in Southern California is imported from the Colorado River and from sources in the eastern Sierra and Northern California via the State Water Project. Several reservoirs are operated primarily for storing surface water for domestic and irrigation use, but groundwater basins are also recharged from the outflow of some reservoirs. The concept is to maintain streamflow over a longer period of time than would occur without regulated flow and thus provide for increased recharge of groundwater basins. Most of the larger basins in this hydrological region are highly managed, with many conjunctive use projects being developed to optimize water supply.

The coastal basins in this hydrologic region are prone to intrusion of seawater. Seawater intrusion barriers are maintained along the Los Angeles and Orange County sections of the coastal plain. In Orange County, recycled water is injected into the ground to form a mound of groundwater between the coast and the main groundwater basin. In Los Angeles County, imported and recycled water is injected to maintain a seawater intrusion barrier.

Table 4.19-N: Well Data Summary for South Coast Hydrologic Region

Well Criteria	# Wells	%
Public Supply Wells Sampled	**2,342**	
Wells Meeting Primary MCL Standards	**1,360**	**58%**
Wells With Constituents Above Primary MCL	**982**	**42%**
Constituents Detected		
Inorganic	118	12%
Radiological	118	12%
Nitrates	373	38%
VOCs / SVOCs	304	31%
Pesticides	69	7%
Most Frequently Occurring Contaminants	**# of Occurrences**

Source: DWR, Bulletin 118, Update 2003.

The chemical character of groundwater in the South Coast region is mainly calcium sulfate and calcium bicarbonate. Nitrate content is elevated in some parts of the subregion. Volatile organic compounds (VOCs) have created groundwater impairments in some of the industrialized portions of the region, particularly the San Gabriel Valley and San Fernando Valley groundwater basins.

The main constituents in the contamination plumes are trichloroethylene (TCE) and tetrachloroethylene (PCE). Some of the locations have been declared federal Superfund sites. Contamination plumes containing high concentrations of TCE and PCE also occur in the Bunker Hill Subbasin of the Upper Santa Ana Valley Groundwater Basin. Some of these plumes are also designated as Superfund sites. Perchlorate is emerging as an important contaminant in several areas in the South Coast region.

Local impairments from excess nitrate or VOCs have been recognized. Groundwater and surface water in the Chino Subbasin of the Santa Ana River Valley Groundwater Basin have elevated nitrate concentrations, partly derived from the area's large dairy industry. In Orange County, water from the Santa Ana River provides a large part of the groundwater replenishment. Wetlands maintained along the Santa Ana River near the boundary of the Upper Santa Ana River and Orange County groundwater basins provide effective removal of nitrate from surface water, while maintaining critical habitat for endangered species.

Groundwater in basins of the San Diego subregion is mainly calcium, sodium, bicarbonate and sulfate based, with local impairments by nitrate, sulfate and TDS. Camp Pendleton Marine Base, in the northwestern part of this subregion, is on the EPA National Priorities List for soil and groundwater contamination by many constituents. From 1994 through 2000, a total of 2,342 public supply water wells were sampled in 47 of the 73 basins and subbasins in the South Coast region. Samples indicated that 1,360 wells (58%) met the state primary MCLs for drinking water. About 42% (982 wells) had constituents that exceeded one or more MCL.

The following basins and subbasins occur within the South Coast Hydrologic Region and underlie areas potentially subject to future development as a result of the proposed project. For a summary of the entire region's groundwater basin data, refer to Table 41 from DWR Bulletin 118, 2003 Update.

Upper Santa Ana Valley Groundwater Basin (No. 8-2): The Upper Santa Ana Valley Groundwater Basin encompasses nine distinct subbasins located along the Santa Ana River running through the urbanized portions of northwestern Riverside County and southwestern San Bernardino County. In total, the basin encompasses nearly 487,000 acres (over 760 square miles) and encompasses the headwaters of the Santa Ana River, which flows south and west into Orange County and ultimately empties to the Pacific Ocean.

Chino Subbasin (No. 8.2-.01): The Chino Subbasin is the largest of the nine within the Upper Santa Ana Valley Basin. It underlies 240 square miles (154,000 acres) mostly in San Bernardino County, plus the northwestern-most corner of Riverside County (generally Eastvale). The subbasin is bounded by the Rialto-Colton Fault on the east and the Jurupa Mountains to the southeast. Puente Hills and the Chino Fault form its southern boundary and the San Bargirel Mountains and Cucamonga Fault bound the subbasin to the north. San Antonio and

Cucamonga creeks drain the surface of the subbasin southward to join the Santa Ana River upstream of the Prado Basin. Showing a coastal influence, annual precipitation ranges from 13-29 inches, with 17 inches average.

The water-bearing geology of the subbasin consists mainly of alluvial fan-shaped deposits ranging up to 150 feet thick near the mouths of the canyons from which the soils originated. In other portions of the subbasin, alluvium is up to 600-700 feet thick. Three major fault systems, including the Rialto-Colton and Cucamonga faults, bound the subbasin in places forming discontinuities in groundwater elevations.

Groundwater recharge to the subbasin occurs by direct infiltration or precipitation on the subbasin floor, by infiltration of surface flow and by underflow of groundwater from adjacent basins. There are also five recharge facilities located within the subbasin along Deer Creek, Day Creek, East Etiwanda, San Sevaine and Victoria. By 1980, groundwater levels within the subbasin had declined about 80 feet from historical high marks in the 1920s. With initiation of the recharge program, however, by 2000 water levels had recovered about 20 feet.

DWR estimates total storage within the subbasin at 18.3 million AF. Water in storage was estimated to be 8.600 million 000 AF in 1982; approximately 5.3 million AF in 1997; and, roughly 5.325 million AF in 2000. The Chino Subbasin was adjudicated in 1978 and pumping within the subbasin is managed by the Chino Basin Watermaster. Total groundwater production in the Chino Subbasin was an estimated 145,700 AF in 1998; 162,300 AF in 1999; 178,800 AF in 2000; and, 161,500 AF in 2001.

Water within the subbasin is predominantly calcium-sodium bicarbonate. Its TDS content ranged from 200-600 mg/L, with an average TDS of 484 mg/L. Title 22 (drinking water) monitoring indicated TDS concentrations ranging from 146-1,710 mg/L, with an average of 359 mg/L. The most serious water pollution problems continue to be high concentrations of dissolved solids and nitrate-nitrogen within the subbasin. Data reported by the DWR indicates that sampling of 149-164 wells found 17 wells with concentrations above an MCL for primary inorganics; 31 for secondary inorganics; 5 for radiological constituents; 73 for nitrates; 6 for pesticides and 10 for VOCs and SVOCs between 1994 and 2000. According to the DWR, the subbasin's elevated nitrate concentrations are generally associated with the area's large dairy industry.

A total of 12 wells are used for groundwater monitoring and 8 wells for water quality monitoring by the USGS and cooperators. Title 22 water quality monitoring is performed on 187 wells. As mentioned previously, the Chino Subbasin was adjudicated in 1978, with a Watermaster responsible for its ongoing groundwater management pursuant to the Optimum Basin Management Program. The Chino Basin Municipal Water District also utilized the subbasin.

Riverside-Arlington Subbasin (No. 8-2.03): This subbasin underlies part of the Santa Ana River Valley in northwest Riverside County and southwest San Bernardino County. It is bounded by the Box Springs Mountains to the southeast, Arlington Mountain to the south, La Sierra Heights and Mount Rubidoux to the northwest and the Jurupa Mountains to the north. It is separated from the adjacent Rialto-Colton Subbasin by the Rialto-Colton Fault. The Santa Ana River flows over the northern portion of the subbasin. Annual average precipitation is approximately 10-14 inches.

The Riverside-Arlington Subbasin is replenished by infiltration from Santa Ana River flow, underflow past the Rialto-Colton Fault, intermittent underflow from the Chino Subbasin, return irrigation flow and deep percolation of precipitation. Groundwater moves northwest near Arlington, then flows southwest to pass through Arlington Gap and into the Temescal Subbasin to the south.

The total storage capacity is estimated at 243,000 AF; 207,000 AF for the Riverside portion of the subbasin and 36,000 AF for the Arlington portion. The amount of groundwater stored in the subbasin is not known.

Municipal water pumping from the Riverside portion of the subbasin was about 10,100 AF in fiscal year 2000-2001, according to the City of Riverside's Public Utilities Department.

Water within the subbasin is predominantly calcium-sodium bicarbonate. Water sampled from the basin's public supply wells had a TDS content ranging from 210-889 mg/L, with an average TDS of 463 mg/L. Information on specific components and concentrations of water pollutants causing impairment is not available. However, data reported by the DWR indicates that of 19-50 wells samples, two showed concentrations above an MCL for primary inorganics; three for secondary inorganics; 11 for radiological constituents; 21 for nitrates; 19 for pesticides and eight for volatile organic compounds (VOCs) and semi-volatile organic compounds (SVOCs).

There are 11 USGS wells for groundwater monitoring and three USGS wells for water quality monitoring, plus an additional 43 wells for water supplies. The subbasin is utilized by the Riverside Public Utilities Department and a portion of the basin is managed by the City of Riverside under an AB 3030 (groundwater management) plan.

San Timoteo Subbasin (No. 8-2.08): The approximately 114-square mile (73,100 acre) San Timoteo Subbasin underlies Cherry Valley and the City of Beaumont in northwestern Riverside County, as well as a portion of southwestern San Bernardino County. The subbasin is bounded to the north and northeast by the Banning Fault and the San Bernardino Mountains, Crafton and Yucaipa Hills, on the south by the San Jacinto Fault and on the west by the San Jacinto Mountains. To the east lies a topographic drainage which demarcates the divide between the South Coast and Colorado River hydrologic regions. The subbasin's surface is drained by Little San Gorgonio Creek and San Timoteo Canyon to the Santa Ana River. Average annual precipitation ranges from 12-14 inches in the western part of the subbasin to 16-18 inches in the eastern part.

Alluvium of unconsolidated clay, silt, sand and gravel for the principal water-bearing geology in this subbasin, with the alluvium being thickest near Beaumont. In some parts of the subbasin, hydrogeological formations are up to 1,500-2,000 feet thick. However, in the central part of the subbasin, water bearing gravels occur at depths of only 700-1,000 feet. Across the subbasin, water levels drop where the presence of various faults disrupt groundwater movement.

Groundwater is replenished by subsurface inflow and percolation of precipitation, runoff and imported water. Runoff and imported water are delivered to streambeds and spreading grounds for percolation. Groundwater flows towards San Timoteo Canyon, then northwesterly along the canyon to Bunker Hill Subbasin. A study of change in water levels during 1933 through 1960 revealed distinctive hydrograph character for wells in alluvial deposits in this subbasin. Hydrographs from wells in San Timoteo Canyon showed a flat character with low yearly fluctuations, those from the northeastern part of the subbasin near Oak Glen showed a flat character with high yearly fluctuations and those from Cherry Valley showed a continual downward trend.

The DWR estimates the total storage capacity of the subbasin's alluvial deposits to be about 2.01 million AF, with the amount of groundwater in storage in 1960 in the alluvial deposits to have been about 1.57 million AF. Deep percolation from irrigation is estimated to be 38,000 AF, from wastewater about 14,000 AF and from precipitation about 16,000 AF. The total subsurface inflow averages about 23,400 AFY. Of this, 21,900 AFY is estimated to come from the San Bernardino and San Gabriel Mountains. Subsurface outflow to the Bunker Hill Subbasin during 1927 through 1967 is estimated to have ranged from 5,350 to 8,150 AFY, with an average of 6,400 AFY.

The subbasin's groundwater tends to be either sodium bicarbonate or calcium bicarbonate in nature, with the calcium form predominant in the younger alluvium and sodium in older deposits. Water sampled from 24 public supply wells have an average TDS content of approximately 253 mg/L, with a range of 170-340 mg/L. As with much of the Upper Santa Ana Valley, high nitrate and salinity levels continue to be of concern. Of the 26-28

wells sampled, only one showed concentrations above MCL for secondary inorganics. No MCL was exceeded for primary inorganics, radiological constituents, nitrates, pesticides, VOCs or SVOCs.

The subbasin has a reported 67 wells used by the USGS for water level monitoring and 12 wells used by the USGS for miscellaneous water quality purposes. A total of 36 wells are monitored for water quality pursuant to Title 22. The subbasin is utilized by the San Bernardino Valley Municipal Water District, San Bernardino Valley Water Conservation District, the City of San Bernardino Water Department and the San Bernardino County Flood Control District, but reportedly no Riverside County agencies. The subbasin is not adjudicated and not reported as being under any groundwater management plans.

Elsinore Groundwater Basin (No. 8-4): This basin covers roughly 40 square miles (25,700 acres) of the Elsinore Valley in western Riverside County. The basin is bounded on the southwest by the Santa Ana and Elsinore Mountains along the Elsinore fault zone. The basin adjoins the Temecula Valley groundwater basin to the southeast and the Temescal subbasin of the Upper Santa Ana River Valley groundwater basin at a constriction in Temescal Wash to the northwest. It is also bounded on the northeast along the Glen Ivy Fault. Lake Elsinore lies within a closed basin formed between strands of the active Elsinore fault zone. Average annual precipitation ranges from 12-14 inches.

The Elsinore Groundwater Basin contains alluvial fan, floodplain and lacustrine water-bearing deposits underlain by alluvium. The maximum thickness of sedimentary deposits reaches 2,300 feet beneath Lake Elsinore. Alluvial fan deposits of gravel, sand, silt and clay are found near the western and northeastern edges of the basin emanating from the adjacent mountains. The interior of the valley contains floodplain deposits that reach a thickness of about 200 feet. In Lake Elsinore's inundation zone, lacustrine deposits reach 800 feet in thickness. Elsewhere in the basin, deposits reach upwards of 2,200 feet in depth.

Groundwater movement in the basin is strongly influenced by faults dissecting the basin's alluvial and lacustrine sediments, with differences in groundwater elevation found across the Wildomar, Willard and Glen Ivy faults. As many as eight separate fault-bounded blocks occur, with little apparent groundwater cross-movement within the basin. The principal recharge of the basin is from infiltration of stream flow through alluvial fan deposits near the edges of the basin and through the gravel deposits along the course of the San Jacinto River. Other contributing sources include infiltration from unlined channels overlying the basin, underflow from saturated alluvium and fractures within the surrounding bedrock mountains and hills, and spreading of water in recharge basins.

The DWR notes that groundwater levels within the basin declined more than 100 feet between 1927 and 1950. A hydrograph from one well shows that water level declined about 110 feet in the southern part of the basin from 1967 through 1985. However, a hydrograph from a well in the northern part of the basin shows a rise in water level of about 65 feet from 1963 to 1981. Under natural conditions, groundwater should flow generally toward Lake Elsinore. However, because the faults cutting the sediments impede groundwater movement, groundwater flow is dominantly contained within fault blocks in the basin.

The total storage capacity of the basin is estimated to be between 1.84 million AF (per the DWR, 1981) and 1.4 million AF (per the EVMWD, 2001). Groundwater in storage (as of the late 1960s-early 1970s) was estimated at 1 million AF. EVMWD estimated approximately 245,000 AF of available dry storage existed in 1999, suggesting that about 1.155 million AF of groundwater in storage was still available. Mean subsurface inflow was estimated at about 800 AFY and, as of 1978, the total annual extraction was roughly 8,100 AF.

The groundwater northeast of Lake Elsinore is calcium sulfate character, whereas groundwater southeast of the lake is calcium bicarbonate and sodium sulfate-bicarbonate character in the central part of the basin. Springs and wells near the City of Elsinore yield water of sodium sulfate character. The range of TDS content for 17 public

wells was 290-680 mg/L, with an average TDS content of 460 mg/L. Some wells also were found to exceed recommended levels for fluoride. Of 18-20 wells samples, one was found to exceed the MCL for primary inorganics and one for VOCs and SVOCs. Secondary inorganics were exceeded for four wells.

The USGS reports using one well for groundwater level monitoring and one for water quality. A total of 18 wells are monitored for Title 22 water quality by DHS and cooperators. The basin is utilized by the Elsinore Valley Municipal Water District (EVMWD), which has proposed a groundwater management plan for the basin.

San Jacinto Groundwater Basin (No. 8-5): The largest basin in western Riverside County, the San Jacinto Basin covers 293 square miles (188,000 acres) in the wide central valley west of the San Jacinto Mountains. The basin is bounded by the San Jacinto Mountains on the east, the San Timoteo Badlands on the northeast, the Box Mountains on the north, the Santa Rosa Hills and Bell Mountain on the south and unnamed hills on the west. Lake Perris is located in the eastern part of Perris Valley and the Diamond Valley Reservoir is located at the edge of the basin to the south. The area's valleys are drained by the San Jacinto River and its tributaries. Average annual precipitation ranges from 10 to 18 inches.

The basin contains sediments that have alluvium-filled valleys and underlying canyons incised into the basement rock. Maximum depths of valley fill reach about 900 feet in the western and northern parts of the basin, but may exceed 5,000 feet in the eastern part of the basin between the Casa Loma and Claremont faults. Confined groundwater is found in the eastern part of the basin between the Casa Loma and Claremont faults, and wells in this basin produce 200-2,600 gpm. The San Jacinto fault zone cuts through the eastern part of the basin, forming five northwest-trending fault segments which act as barriers to groundwater movement.

Natural recharge to the basin is primarily from percolation of flow in the San Jacinto River and its tributary streams; less recharge is from infiltration of rainfall on the valley floor. The primary recharge area for the confined aquifers is found where the San Jacinto River and Bautista Creek enter the San Jacinto Valley. Natural recharge is augmented by spreading of imported SWP water and reclaimed water through infiltration ponds in the upper reaches of the San Jacinto River. Percolation of water stored in Lake Perris has been an additional source of recharge since construction of the lake in the 1970s. Reclaimed water also percolates through several storage ponds distributed throughout the valley. Artificial recharge can exceed natural recharge, particularly in years with low precipitation.

Prior to the extraction of groundwater from the basin, groundwater flow was generally toward the course of the San Jacinto River and westward out of the basin. High extraction rates, however, have produced groundwater depressions and locally reversed the historical flow pattern. During the 1960s, groundwater levels in the western and central parts of the basin declined; whereas, in the south-central part of the basin, they were moderately stable. During the 1970s through the 1990s, groundwater levels declined about 20-40 feet in the northern and southeastern parts of the basin, but were relatively stable in the southern part of the basin. During the 1970s through the 1980s, groundwater levels rose 80-200 feet in the western part of the basin because of infiltration from Lake Perris. In the early 2000s, groundwater levels generally rose in the central part of the basin and declined in the northeastern and southern parts of the basin.

The estimated groundwater storage capacity of the San Jacinto Basin is 3.07 million AF and, in 1975, the calculated groundwater in storage was 2.7 million AF. EMWD gathers and compiles groundwater production and artificial recharge amounts for the basin and reports annually. Groundwater production in the portion of the basin managed under the West San Jacinto Groundwater Management Plan is estimated at 18,880 AF for 2001 and 20,058 AF for 2002. Estimates of extraction for the entire basin between 1984-1999 range from 60,400 AFY to 100,100 AFY, with an average of about 78,700 AFY. Between 1,000 and 1,300 AF of reclaimed water are recharged each year. About 5,800 AF of SWP water were recharged in 2002, but none was recharged in 2001.

Infiltration of San Jacinto River flow ranged between 4,500 and 191,600 AF from 1984 to 2000, with an average of 46,900 AFY.

Historically, the basin's groundwater was of good quality for domestic, irrigation and industrial purposes. The groundwater was typically sodium bicarbonate, calcium bicarbonate or sodium chloride in character, or combinations thereof. Historically, groundwater in the basin typically had a TDS content less than 1,000 mg/L. In 2002, TDS content ranged from 230-12,580 mg/L and the maximum TDS content exceeded 1,000 mg/L in most parts of the basin. Data from 51 public supply wells show TDS content in the basin ranges from 160 to 1,390 mg/L and averages about 463 mg/L.

Historically, high levels of boron and fluoride were found in the central and northwest parts of the basin, and high nitrate-nitrogen concentrations were found in the southeast part of the basin. In 2002, groundwater exceeding a nitrate-nitrogen concentration of 10 mg/L was found in wells throughout most of the basin. Nitrate-nitrogen concentrations as high as 40 mg/L were found in the northern part of the basin in the 1990s and as high as 28 mg/L in the southern part of the basin in 2002. In 2002, TDS content was measured as high as 12,580 mg/L in the basin and wells with TDS content exceeding 1,000 mg/L were found throughout most of the basin. DWR notes that pumping is causing groundwater of high TDS content to move from the western part of the basin into groundwater of lower TDS content in the central part of the basin. However, remediation efforts have helped slow the migration of this plume.

Of 54-56 wells sampled, concentrations above MCL were found for primary inorganics in three wells, secondary inorganics in 15 wells, radiological constituents in two wells, nitrates in 12 wells and pesticides in one well. EMWD monitors 169 wells for groundwater levels and 113 for water quality. A total of 56 wells are monitored for Title 22 water quality. In addition to EMWD, the basin is used by the Lake Hemet Municipal Water District. Most of the basin is managed under the jurisdiction of the West San Jacinto Groundwater Basin Management Plan, an AB 3030 plan adopted in 1995.

Temecula Valley Groundwater Basin (No. 9-5): This basin covers 137 square miles (87,800 acres) of southwestern Riverside County and northwestern San Diego County. The valleys of Murrieta, Temecula, Pauba, Long and Lancaster are the largest of the overlying valleys. The basin is bounded by the Peninsular Ranges and the overlying valleys are drained mainly by Wilson, Temecula, Murrieta, Warm Springs and Pechanga creeks to the Santa Margarita River, which flows west out of the Temecula Valley. The Pechanga Indian Reservation overlies some of the southwestern part of the basin. Average annual precipitation ranges from 7-15 inches.

Alluvium reaching more than 2,500 feet thick is the main water-bearing material of this basin. Well yields generally range to 300 gpm in the northwestern part of the basin, but reach 1,750 gpm for wells in Pauba Valley. The Lancaster, Aguanga and Agua Caliente faults, as well as several strands of the Elsinore fault zone, cross the basin and may affect groundwater movement. The Wildomar Fault, in particular, forms a groundwater barrier that produces differences in water level and pressure in the northwestern part of the basin. Murrieta Hot Springs lies along an unnamed fault indicating that the fault affects subsurface flow.

Natural recharge of the alluvium is from direct precipitation and percolation in the Warm Springs, Tucalota, Santa Gertrudis, Murrieta and Pechanga creeks and the Temecula River. Groundwater flows southeastward under Murrieta and Temecula valleys and southwestward beneath Pauba Valley to the southwestern part of the basin. In the central part of the basin, the water level in one well rose about 12 feet between 1990 and 1994. In the southwestern part of the basin, the water level in one well declined about 60 feet between 1980 and 1992, recovered about 50 feet in 1993 and then declined another 15 feet between 1994 and 2001. The hydrograph of another well in the southwestern part of the basin indicates large seasonal variations in water levels. The total

groundwater storage capacity of the basin is estimated at 253,000 AF. The amount actually stored in the basin is unknown. Groundwater extraction was about 13,000 AF in 1953.

The groundwater in this basin is largely sodium bicarbonate in character, though sodium-calcium bicarbonate, sodium-calcium sulfate, calcium bicarbonate and sodium chloride waters also are present. TDS concentration ranged from 220-984 mg/L in 1956. Water from 50 public supply wells ranged from 240-1,500 mg/L and averaged 476 mg/L. Groundwater in this basin is largely suitable for domestic and irrigation uses. The groundwater is rated inferior for domestic use, however, locally near Murrieta and Murrieta Hot Springs because of high nitrate or fluoride content. It is rated as marginal to inferior for irrigation use locally in the Pauba and Wilson Creek valleys and near Murrieta Hot Springs, because of chloride content and percent sodium. Sulfate, chloride, magnesium and nitrate concentrations are locally high for domestic use; TDS content is locally high for domestic and irrigation use.

A number of wells are monitored groundwater levels monthly by various agencies: 115 wells by RCWD, 17 wells by USGS, five by Murrieta County Water District and three by EMWD. The USGS also monitors water quality for four wells and 67 wells are monitored for water quality pursuant to Title 22. Public water agencies using the basin include EMWD, EVMWD and RCWD. Murrieta County Water District also developed a Watershed Management Plan under AB 3030.

Cahuilla Valley Groundwater Basin (No. 9-6): This small basin covers roughly 28 miles (18,200 acres) underlying the Cahuilla and Anza valleys in southern Riverside County. This inland basin lies within the Peninsular Ranges and abuts the boundary with the Colorado River Hydrologic Region. It is bounded by the Peninsular Ranges and its northeastern boundary is the San Jacinto fault zone. Cahuilla Creek drains surface water westward toward the Pacific Ocean. Average annual precipitation ranges from 7-15 inches.

The water-bearing units within the basin are alluvium, older alluvium and weathered residuum (soil formed from crumbled/eroded rock). The maximum thickness of the alluvium is estimated to be from 550 feet to less than 200 feet. Well yields range from less than 25 gpm to 500 gpm. Splays of the San Jacinto fault zone cut through and abut the eastern edge of the basin and probably inhibits subsurface flow. Water level contours are offset by as much as 140 feet along a north-trending structure along the west edge of Anza Valley, implying that a fault restricts groundwater flow at that location. Water level contours indicate that movement of groundwater is generally towards Cahuilla Creek, then west, following the course of the creek. A comparison of water level contours for 1950 and 1973 indicated that a widespread pumping depression developed by 1973 in Anza Valley. Water levels were depressed as far as 70 feet below their 1950 level. The total storage capacity of the basin is estimated at about 75,000 AF. The total amount of groundwater in storage is unknown nor is water budget information available, according to the DWR.

The character of groundwater in this basin ranges from a sodium-calcium bicarbonate to sodium chloride. TDS concentrations ranged from 304-969 mg/L. Locally, sulfates and nitrates are high for domestic use, with nitrate concentrations reaching as much as 128 mg/L. The private Anza Mutual Water Company monitors groundwater levels monthly in two wells and one well is monitored for water quality per Title 22 standards. The basin is also used by the Cahuilla Indian Reservation.

C. Other Local Water Resources in Riverside County

In addition to imported water and locally produced groundwater, there are a number of additional avenues local water agencies may utilize to increase their water supply and improve the quality of existing supplies. Key sources of additional water include recycled and reclaimed water, stormwater capture and management, as well as

graywater and other 'new' sources. Each of these water types are described generally, below. In the water district accounts, which follow, further details are provided on the specifics utilized by the individual agencies.

Programs to help bridge the gap between supply and demand include urban conservation programs, agricultural efficient water management practices, reclamation, recycling, desalination of brackish groundwater and seawater, groundwater recharge with reclaimed or raw surplus water, and transfers of water from agricultural to urban uses.

1. Surface Waters

As seen above, groundwater basins tend to occur in valleys as a result of the geology of the surrounding bedrock and mountains. Surface waters follow similar geological features to form watersheds. But since gravity dictates where these waters flow, topography also plays an important part in defining watersheds. The hydrology of Riverside County on a regional basis was discussed previously in Section 4.19.2 (Hydrology). This section specifically summarizes those surface waters that are used to supply water locally to various agencies within Riverside County.

Within the South Coast Hydrologic Region, the Santa Ana, San Jacinto and Santa Margarita rivers, and their various tributaries, are the major waterways within Riverside County. In terms of surface water supplies, the San Jacinto River is used by the Lake Hemet Municipal Water District (LHMWD). According to the 2005 LAFCO report, LHMWD maintains Lake Hemet, which releases into the San Jacinto River, as a water reservoir and recreational facility. The San Jacinto River supplies an average of 3,600 AFY to LHMWD, approximately 20% of the district's total water supply. LAFCO states that most of the surface water is used for agricultural purposes, but a portion is conveyed to LHMWD's Eggen Water Treatment Plant for treatment prior to domestic use.

Within the Upper Santa Margarita watershed, the Seven Oaks reservoir delivers surface water to various treatment plants and to spreading ponds for groundwater recharge, including: potable at Canyon Lake; non-potable at Lee Lake, Temescal Wash, Horsethief Canyon and Indian Canyon. Major surface water sources in the watershed include MWD's Diamond Valley Lake and Lake Skinner reservoirs.

Surface waters and groundwater supporting surface water in the Santa Margarita watershed have been under some form of court jurisdiction since 1928. A Watermaster assigned by the U.S. District Court for the Southern District of California oversees all water uses within the Santa Margarita watershed, although specific water rights in the watershed have not been adjudicated. However, a Stipulated Judgment assigns two-thirds of all natural waters to the United States of America (Camp Pendleton) and the remaining one-third to Rancho California Water District (RCWD). Rights to utilize the water and groundwater stored in Vail Lake are defined in the 1940 Stipulated Judgment in the case of Santa Margarita versus Vail and Appropriations Permit 7032 issued by the State Water Resources Control Board (SWRCB). RCWD stores local runoff in Vail Lake, which was created in 1948 through construction of Vail Dam on Temecula Creek. RCWD has a surface water storage permit in Vail Lake for up to 40,000 AF from November 1 to April 30. During these months, RCWD releases available water from Vail Lake to the Valle de los Caballos (VDC) spreading basins, about 1.5 miles downstream, for groundwater recharge. From May through October, existing state permits prohibit storage and require inflow to pass through Vail Lake to Temecula Creek and ultimately to the lower watershed.

Upstream on the Santa Ana River, in San Bernardino County, water from the Seven Oaks dam (reservoir) is also used by WMWD and SBVMWD. LAFCO reports that the City of Riverside also has water rights to this body but is not using them at present. Lastly, the Yucaipa Valley Water District (YVWD), which serves portions of Riverside County in addition to San Bernardino County areas, also uses surface water from both Wildwood Canyon and Oak Glen. The Beaumont-Cherry Valley Water District also has diversion rights to Little San Gorgonio Creek.

Two other man-made surface water sources are also used to supply local water in western Riverside County. Canyon Lake, more specifically Railroad Canyon Reservoir, impounds local runoff from the 750-square mile San Jacinto River watershed and is used by Elsinore Valley Municipal Water District (EVMWD). A second man-made reservoir, Corona (Lee) Lake, along Temescal Wash, also provides surface water to EVMWD as part of the 6,000-7,000 AF produced annually in the region.

Within the Colorado River Hydrologic Region, the Whitewater River and its tributaries, in addition to the Colorado River, are the major waterways within eastern Riverside County. The Whitewater River is a minor (less than 2,000 AFY) source of surface water for the Desert Water Agency (DWA). No other agencies take surface waters directly within the Coachella Valley or the rest of eastern Riverside County. Surface water from the Whitewater River is also provided to the City of Banning through the Banning Bench Mutual Water Company according to LAFCO.

In the San Jacinto Mountains that lie between eastern and western Riverside County, two of the four water agencies that serve the area access surface waters. (None of these four import water.) According to LAFCO, the Fern Valley Water District (FVWD) uses surface water diversions from Strawberry and Tahquitz creeks, supplemented by local groundwater, as its retail water source to serve its 1,200 connections. FVWD is allowed to divert 0.48 cfs from the creeks for use within 30 days and 30 AFY for seasonal storage. The Idyllwild Water District (IWD) also diverts surface water from Strawberry Creek (at Foster Lake) for use in groundwater recharge according to LAFCO. IWD is permitted to store 40 AFY on Lilly Creek and has the right to use water from the creek for domestic, recreational and fire protection uses. IWD may also store surface runoff from the watershed in Foster Lake during the fall, winter and spring seasons according to LAFCO.

2. Recycled Water

Recycled water is water that as a result of tertiary treatment of domestic wastewater by a public agency is suitable for a direct beneficial use or a controlled use that would not otherwise occur. (*Note:* As provided in CWC Section 26, 'recycled water' or 'reclaimed water' has the same meaning the definition of recycled water given in CWC Section 13050(n)). The level of treatment and quality of the reclaimed water shall be approved by the public health authority having jurisdiction. DWR and the local water agencies serving the area covered by GPA No. 960 support the implementation of a variety of water resource programs, including reclaimed and recycled water programs. The Reclamation, Recycling and Water Conservation Act of 1996 authorized federal cost-sharing in wastewater recycling projects and includes funding for desalination of sea water and groundwater, reclaimed water treatment and reuse.

State Water Resources Control Board policy encourages substitution of recycled water in place of potable water where possible. There is a set of strict regulations that govern its uses which are designed to protect the existing and proposed designated beneficial uses of the receiving ground or surface water. The Santa Ana River, San Diego and Colorado River RWQCBs have Water Quality Control Plans for their respective watersheds. They contain water quality objectives for the groundwater basins and for the surface waters. Any use of recycled water which results in planned recharge of an aquifer or discharge into a surface water must meet the water quality standards set forth by these objectives and/or have prior approval from the RWQCB. See Section 4.19.5 for discussion of these water quality control plans.

Recycled water can be used to recharge aquifers for future potable water supply use and also used to stop intruding higher TDS water from contaminating a groundwater basin as in the prevention of salt water intrusion along the coast or the boundary between a basin of poor quality and a basin of good quality. The TDS of recycled water is directly related to the TDS of the domestic water supply. Recycled water typically has mineral

salt (TDS) levels approximately 200 to 250 mg/L higher than the potable source water. In order to have high-quality recycled water, high quality source water or desalination is required.

As described in MWD's 2010 RUWMP, local water recycling projects involve further treatment of secondary-treated wastewater that is currently discharged to the ocean or streams and lands and also its direct non-potable use for areas, such as landscape and agricultural irrigation, commercial and industrial purposes, as well as for indirect potable uses, such as groundwater recharge and surface water augmentation. Many local agencies collect and treat municipal wastewater, including EMWD, CVWD and WMWD. MWD's service area, which covers much of Southern California (see Figure 4.19.18), uses about 308,000 AFY of recycled water; 132,000 AFY for irrigation, 15,000 AFY for industrial processes and 118,000 for groundwater recharge operations. However, existing water quality and regulatory issues limit groundwater recharge using recycled water, as does the need for high-quality potable water for blending in order to meet specified water quality targets. Recycled water use is growing rapidly in Riverside County and elsewhere in MWD's service area. However, further expansion depends on progress in research, regulatory change, public acceptance and financing of local projects.

CVWD and others also utilize recycled wastewater and recognize its significant potential as a local resource that could be expanded to help reduce current local overdraft problems. Continued urban growth in the CVWD service area is generating increased wastewater and is expected to generate more in the future. As areas not currently served by wastewater facilities continue to grow, the agencies serving those areas will need to extend their wastewater collection systems as well. CVWD's West Valley service area is already using all of its treated municipal wastewater for irrigation or percolation ponds, and the demand for non-potable water is currently greater than the supply. However, little wastewater reuse is occurring in eastern Coachella Valley. According to CVWD's 2011 Management Plan Update, as population growth continues, significantly more wastewater will be generated, providing an important source of additional water that could be treated and then used to further offset groundwater pumping.

Within the Upper Santa Margarita watershed, recycled water is produced by four water service providers. Currently, there are no uniform criteria for regulating groundwater recharge applications. DHS requires blending recycled water with at least an equal amount of non-recycled water. Water recharged in this manner must be retained for a minimum of six months in the ground prior to extraction for drinking water. Additionally, no extraction can occur within 500 feet of a recharge site. RCWD has a contract with EVMWD to provide effluent from the Santa Rosa Water Reclamation Facility. From 2008 to 2012 the requirement is 1.5 cfs; in 2013 the requirement increases to 2.3 cfs. Recycled water produced in the upper watershed by EMWD and RCWD in excess of demands is sent to the Temescal Wash for discharge into the Santa Ana watershed. Water quality regulations in the Santa Margarita watershed have made disposal of excess recycled water in the Santa Margarita watershed cost prohibitive. Recycled water quality in the upper watershed is treated to meet regulatory standards and end user requirements. Recycled water must be of sufficient quality to not detrimentally damage landscaping and agriculture. Each of the water providers actively engages in nitrogen and salinity management.

3. Desalination

The federal Reclamation Recycling and Water Conservation Act of 1996 authorized federal cost-sharing in wastewater recycling projects and included funding for desalination of sea water and groundwater, reclaimed water treatment and reuse. The federal Water Desalination Act of 1996 encourages desalination research by providing funding for exploration of this developing technology. As discussed in MWD's 2010 RUWMP, seawater desalination especially represents a significant opportunity to diversify the water resource mix available to Southern California, including Riverside County, with a new, locally-controlled, reliable potable water supply. Like conservation, recycling and other new local supplies, seawater desalination will increase regional supply reliability by offsetting existing and future demands for imported water. MWD is aiming for 150,000 AFY of

seawater desalination by 2025 and several other local and retail water agencies have also identified seawater desalination as an important component of their water supply portfolios in their UWMPs.

The implementation of large-scale seawater desalination plants in California offers many opportunities and challenges. In the past decade, advances in energy efficiency and membrane technology have reduced the cost of seawater desalination relative to costs for imported water supplies and other supply alternatives. Challenges to seawater desalination include high capital and operation costs, pre-treatment design constraints, environmental issues, system integration needs and an unpredictable permitting process. MWD and MWD's member agencies are actively pursuing research into alternative intake and outfall technologies, process designs and treatment alternatives that could minimize some of the environmental issues and lower unit costs. These advances continue to make increased seawater desalination a viable option for a new water supply.

In addition to seawater desalination, desalination can also help manage problems with high TDS in groundwater and drainage water. CVWD, for example, is developing facilities for treating agricultural drainage water. It has plans for a drain water desalination facility to commence operation by 2015, which would increase the non-potable water supply for irrigation of agriculture, golf courses and landscaping, as well as for groundwater recharge. The West San Jacinto Groundwater Basin within EMWD's service area has high TDS groundwater. Because of decreased production, it is experiencing increased water levels, which causes migration of saltier water into areas of higher quality groundwater. To prevent this, EMWD has implemented a Groundwater Salinity Management Program, which consists of two desalination facilities which they own and operate (EMWD UWMP, pages 49-55). These facilities address groundwater migration problems and supply additional water for potable use. Extraction capacity will be increased by the completion of construction scheduled for September 2011. A third facility has been designed and is projected to be on line in 2015.

4. Water Transfers

The least expensive and most efficient of the above-listed types of programs is the transfer of water from agricultural to urban uses. In recent years, municipal population growth and the need for water supply reliability have triggered the growth of water transfer programs. MWD, for example, has entered an agreement with farmers in the PVID for a transfer of just under 186,000 AF of Colorado River water from farmers to MWD over a two-year period. MWD has paid the equivalent of $143 per AF of water to farmers. In order to make this amount of water available for the transfer, the farmers have left approximately 20,215 acres of farmland fallow. Other types of water transfers also increase the predictability and reliability of water supplies. For example, MWD has storage and transfer programs with CVP and SWP settlement contractors, which allow MWD to purchase water in drier years for delivery to MWD's service area. MWD has developed a number of Central Valley/ SWP storage and transfer programs, which have enabled it to meet its 2010 dry-year resource target and to protect against potential water shortages due to decreases in the Colorado River supply and as a result of drier-than-expected hydrologic conditions.

EMWD relies on MWD's water transfers and exchanges, but is also investigating opportunities independent of transfers and exchanges as a method of improving reliability, especially during periods of water shortages. Per the 2011 Management Plan Update, CVWD has likewise not identified any specific independent transfer projects, but recognizes that it could pay for development of a new water source or installation of water conservation devices or recycled water delivery systems in another water district elsewhere in California in exchange for transferring the water to CVWD (page 6-18). More agreements which transfer water from agricultural to urban uses are expected, as well as those from water-rich agencies to those agencies with a supply shortage.

5. Stormwater and Runoff Capture and Management

Stormwater capture is another method that has been identified as having the potential for development as a 'new' water source for augmenting local water supplies. Because of the arid nature of much of Riverside County, many drainage areas have little or no flow except immediately after storm events, which happen largely in the winter. In the CVWD service area, significant amounts of local runoff are currently captured at the Whitewater River Recharge Facility and in the debris basins and unlined channels of the west valley. Additional stormwater will be captured when the 1000 Palms Flood Control Project is completed and when flood control improvements are constructed in the Oasis area. Stormwater capture potential is also being considered in conjunction with projects that construct stormwater and flood control facilities. In addition, flood control agencies within MWD's service area have for many years captured and spread stormwater for groundwater replenishment. Local runoff, like reclaimed water, is also conserved via spreading grounds, injection wells, reservoirs and unlined river channels.

6. Graywater

Graywater represents another potential local water source. This type of water is wastewater generated from domestic activities, such as laundry, dishwashing, bathing and other non-sewage uses, and can be recycled (with or without further purification) for onsite uses, such as landscape irrigation or drainage into constructed wetlands. It is important to note that graywater is not sewage (blackwater) and does not contain human waste. As it is wastewater, however, it is regulated differently than potable water sources since it can contain impurities including pathogens.

In July 2009, the California Building Standards Commission (CBSC) approved the addition of Chapter 16A, "Non-Potable Water Reuse Systems," to the 2007 California Plumbing Code. Emergency regulations allowing graywater reuse systems were subsequently filed with the California Secretary of State August 2009 and became effective immediately upon filing. Assembly Bill 371 (Goldberg 2006) and Senate Bill 283 (DeSaulnier, 2009) directed DWR, in consultation with the State Department of Health Services, to adopt and submit to the CBSC regulations for a State of California version of Appendix J (renamed Chapter 16 Part 2) of the Uniform Plumbing Code to provide design standards to safely plumb buildings with both potable and recycled water systems. November 2009 the CBSC unanimously voted to approve the California Dual Plumbing Code that establishes statewide standards for installing both potable and recycled water plumbing systems in commercial, retail and office buildings, theaters, auditoriums, condominiums, schools, hotels, apartments, barracks, dormitories, jails, prisons and reformatories. In addition, the California Department of Housing and Community Development has graywater standards and DWR has also proposed dual plumbing design standards. MWD and some of the other water agencies serving Riverside County have provided comments on these developments and continue to explore options for graywater capture and usage.

D. Wholesale and Retail Water Agency Perspectives

As part of the effort to gather and summarize water supply related to the proposed project, GPA No. 960, data was gathered from a variety of state, regional, county and local resources. The water resource analyses provided herein were developed in part by reviewing and utilizing the current and detailed information and analyses set forth in documents such as, but not limited to: the 2009 California Water Plan Update (CWP) prepared by the California Department of Water Resources (DWR); the 2010 Regional Urban Water Management Plan prepared by the Metropolitan Water District of Southern California (MWD); Integrated Regional Water Management Plans prepared through the cooperative and collective efforts of water supply agencies in Riverside County; and the 2010 Urban Water Management Plans (UWMPs) prepared by individual urban wholesale and retail water suppliers throughout Riverside County, and, in particular, those serving areas potentially affected by GPA No.

960. As indicated above, these are the types and categories of source documentation that the County of Riverside is instructed to utilize for purposes of preparing the water supply analysis for revising its General Plan pursuant to GPA No. 960. (See, e.g., CGC Sections 65302.2 and 65352.5). In addition to being summarized and discussed throughout the following section, additional information from these documents is also included in Appendix EIR-8, as noted.

1. Urban Water Management Plans

The discussion below begins from the regional perspective of MWD. As the largest single water provider in California and the State Water Contractor (SWC) serving western Riverside County, information from the MWD's 2010 Regional Urban Water Management Plan (RUWMP) establishes a relevant, comprehensive and detailed overview of the issues affecting water supply and demand in large areas of Riverside County affected by GPA No. 960. Then, focusing on specific portions of western Riverside County, sections are presented for the Eastern Municipal Water District (EMWD) and Western Municipal Water District (WMWD), both of which are MWD member agencies that provide wholesale, as well as retail, water services within their respective service areas.

Also, sections are presented for the Coachella Valley Water District (CVWD) and Desert Water Agency (DWA), two State Water Contractors that supply wholesale water in eastern Riverside County. Two additional water supply agencies, the Pine Cove County Water District (PCCWD), which serves a portion of the San Jacinto Mountains, and the Palo Verde Irrigation District (PVID), are also discussed. Following those discussions, additional information and analyses related to specific retail water agencies are provided. For example, information on the Rancho California Water District (RCWD) is presented since, although a member-agency of EMWD, it is explicitly not covered under EMWD's UWMP and it imports a portion of its water supply directly from MWD.

In this way, all of the State Water Contractors (agencies receiving SWP supplies pursuant to a direct contract with DWR) that provide water service in Riverside County are discussed in this section, with the exception of the San Gorgonio Pass Water Agency (SGPWA). Other than approximately 300 acres of vacant land to be designated as Open Space – Habitat Conservation (OS-CH) for habitat conservation, which would not affect water supply or demand for purposes of this analysis, SGPWA does not provide water service any areas affected by GPA No. 960. Lastly, separate information and analyses are presented for the areas not covered by existing water service providers. These areas, which would require self-service (for example, private wells), are discussed according to County Area Plan in which they are located and their respective proximities to an identified groundwater basin, as applicable. See Section 4.19.4.I-3, for more information.

2. Relationship Between the General Plan and the Urban Water Management Plans

In accordance with applicable law, much of the information and analyses set forth in this water supply analysis for GPA No. 960 has been prepared by utilizing the detailed data and descriptions recently prepared by urban water suppliers throughout Riverside County regarding the sufficiency of their total projected water supplies to serve existing and projected demands over the next 20-year planning horizon and beyond during normal, single-dry and multiple dry-year periods. Indeed, the State of California's general plan laws include several provisions which show a key relationship between the general planning process and information developed by local water supply agencies, particularly UWMPs. For example, CGC Section 65302.2 provides that when adopting or revising its general plan, a county must utilize as a source document any UWMP that is submitted to it by a water agency. Prior to adopting or substantially amending a general plan, the planning agency is required to refer the proposed

action to various agencies, including public water systems that serve water to customers within the area covered by the proposal (CGC Section 65352(a)(7)).

In accordance with these provisions of the general planning laws, in August 2010 the Riverside County Planning Department submitted letters to the public water systems throughout the areas covered by GPA No. 960, informing such agencies about Riverside County's proposed action to adopt or substantially amend its general plan and requesting certain water-related information. (A sample copy of the letters submitted by the Riverside County Planning Department is included in Appendix EIR-8.) In response to Riverside County's letters, a number of water agencies provided the County of Riverside with a variety of water supply and demand information such as that set forth in Government Code Section 65352.5(c). In several cases, the County of Riverside received the most recently prepared version of the water agency's UWMP, since most, if not all, of the information specified in Section 65352.5 is included in an UWMP.

The Urban Water Management Planning Act, CWC Section 10610 *et seq.* (UWMP Act), is "intended to provide assistance to water agencies in carrying out their long-term resource planning responsibilities to ensure adequate water supplies to meet existing and future demands for water." (CWC Section 10610.2(b)). The UWMP Act requires every 'urban water supplier' to prepare and adopt an updated Urban Water Management Plan (UWMP) at least once every five years by December 31st in years ending in five and zero. For purposes of the UWMP Act, an urban water supplier is defined pursuant to CWC Section 10617 as "a supplier, either publicly or privately owned, providing water for municipal purposes either directly or indirectly to more than 3,000 customers or supplying more than 3,000 AF of water annually. An urban water supplier includes a supplier or contractor for water, regardless of the basis of right, which distributes or sells for ultimate resale to customers."

According to the UWMP Act, a UWMP must address, among other things, projected water use, the reliability of water supply sources, the potential for using reclaimed water and desalinated water, water shortage contingency planning, comparisons of supply and demand, and water conservation efforts. (See CWC Sections 10631-10635). Specifically, the UWMP Act (CWC Section 10631) requires urban water suppliers to document water supplies available during normal, single-dry and multiple-dry water years in five-year increments over a 20-year period or more, as well as the existing and projected future water demands associated with forecasted population increases throughout the water provider's service territory over the same minimum 20-year period.

A UWMP must describe the service area of the supplier, including current and projected population, climate and other demographic factors affecting the supplier's water management planning. (CWC Section 10631(a)). The UWMP must quantify past, current and projected water use in 5-year increments, identifying the uses among various water use sectors, including single-family residential, multifamily, commercial, industrial, institutional and governmental, landscape, sales to other agencies, seawater intrusion barriers, groundwater recharge, conjunctive use, or any combination thereof, and agricultural use (CWC Section 10631(e)(1)). A UWMP must also describe the reliability of the water supply and its vulnerability to seasonal and climatic shortage, as well as provide data to the extent practicable for average, single-dry and multiple-dry water years (CWC Section 10631(c)(1)). Notably, Section 10631(k) of the UWMP Act allows agencies to 'rely' on information and analyses provided by wholesale water agencies regarding the availability and reliability of water supplies during normal, single-dry and multiple-dry year periods over the 20-year planning horizon.

Given the level of detail and information required in a UWMP, these documents can significantly reduce the burden of preparing a general plan water supply analysis for purposes of CEQA (Vineyard, 40 Cal.4th 412 at 434; Sonoma County Water Coalition, 189 Cal.App.4th 33 at 53-54; Watsonville Pilots Association, 183 Cal.App. 4th 1059 at 1092-93). As indicated above, the UWMP Act requires a qualifying urban water supplier to prepare and adopt an updated UWMP at least once every five years in years ending in five and zero. However, the Water Conservation Act of 2009, CWC Section 10608 *et seq.* (SBX7-7) and SB 1478 extended the time by which urban

retail water suppliers must adopt their 2010 UWMPs to July 1, 2011. Thus, from a timing perspective, the preparation of this water supply analysis for GPA No. 960 coincides with the recent preparation and adoption of current UWMPs by water supply agencies throughout Riverside County. Accordingly, and particularly for purposes of CGC Section 65302 *et seq.* (i.e., instructing a county to use UWMPs as source documents when adopting or revising a general plan), this analysis is based on the best and most current information available regarding long-term water supply sufficiency in the areas affected by GPA No. 960. It should be noted, that in order to manage the voluminous information associated with water supplies in general, and affected water agencies, in particular, information is presented in summary in this EIR chapter with additional supporting details provided in Appendix EIR-8.

3. Relationship Amongst Local Water Providers and Water Sources

Because water comes from a variety of sources (surface, groundwater, reclaimed) both locally and from imports, understanding the relationship between the various water providers and their sources can be challenging. To simplify these relationships, Riverside LAFCO provided schematics of the water supplies for Western and Eastern (Coachella Valley) Riverside County, as well as the San Gorgonio Pass / San Jacinto Mountain areas of Riverside County. These schematics are provided in Figures 4.19.15, 4.19.16 and 4.19.17, above.

In the following section, more detailed information is provided on the Metropolitan Water District of Southern California, as it is the SWP water importer Southern California and the source of imported water for all of western Riverside County. Likewise, detailed information is provided on the Coachella Valley Water District, which is the major water importer and wholesaler (Colorado River and SWP water) for eastern Riverside County. Secondarily, a summarization of key details for the major water wholesalers serving Riverside County internally are provided (Eastern and Western Municipal Water Districts for western Riverside County and the Desert Water Agency for the east).

Summary information is also presented for the San Gorgonio Pass Water Authority (Riverside County's other State Water Contractor), as well as for the three water districts (Pine Cove, Idyllwild and Fern Valley) serving the Idyllwild / central mountain region of Riverside County. These districts are included because they directly serve their portions of Riverside County via ground and surface waters; they do not import any water. Also, the Palo Verde Irrigation District (PVID), which does not provide any potable water, only agricultural water from the Colorado River, is discussed. Lastly, the retail water agencies are covered briefly. For each district, more information is generally provided in Section 4.19.4.F.

E. Metropolitan Water District of Southern California

The Metropolitan Water District of Southern California (MWD) is the largest water district in the state. It is comprised of 26 member agencies, including fourteen cities, ten other municipal water districts and one county water authority and serves more than 143 cities. To facilitate and ensure coordination between itself and its member agencies, MWD adopted its Final 2010 Regional Urban Water Management Plan (RUWMP) in December 2010.

MWD's 2010 RUWMP outlines a variety of issues related to water supply, demand and reliability. The RUWMP examines projected water demands on MWD's water supply and the availability of that supply under normal and dry years as indicative of water supply adequacy. It also outlines plans and programs relating to water conservation and best management practices, water quality and other programs aimed at ensuring existing water supplies are used responsibly and that future water supplies are available as growth increases demand for potable water. Unless otherwise noted, the information summarized in this section is from MWD's 2010 RUWMP.

1. MWD Service Area

MWD is a public agency organized in 1928 by a vote of electorates of thirteen Southern California cities. The agency was created by the original Metropolitan Water District Act (Metropolitan Act; California Statutes 1927, Chapter 429, as reenacted in 1969 as Chapter 209) by the California legislature "for the purpose of developing, storing and distributing water" to the residents of Southern California. Pursuant to its enabling act, MWD is authorized to levy property taxes within its service area, establish water rates, impose charges for water standby and service availability, incur general obligation bonded indebtedness and issue revenue bonds, notes and short-term revenue certificates, execute contracts and exercise the power of eminent domain for the purpose of acquiring property. In 1992, the MWD Board of Directors adopted the following mission statement: "To provide its service area with adequate and reliable supplies of high-quality water to meet present and future needs in an environmentally and economically responsible way."

MWD's service area includes the Southern California coastal plain. It extends about 200 miles along the Pacific coast from Oxnard in the north, to the Mexican border on the south and reaches more than 70 miles inland. The service area includes portions of Los Angeles, Orange, Riverside, San Bernardino, San Diego and Ventura Counties. Approximately 90% of the population within these counties is within MWD's boundaries. MWD member agencies serve more than 143 cities and 89 unincorporated areas. Figure 4.19.18 shows MWD's service area.

MWD is a wholesale provider only and has no retail customers. It provides treated and untreated water directly to its member agencies. The 26 member agencies then deliver to their customers a blend of groundwater, surface water, desalinated water, recycled water and imported water from MWD. MWD has provided between 45-60% of the municipal and agricultural water used in its nearly 5,200-square mile service area. The remaining water is provided through local resources and imported water from other sources. Member agencies receive deliveries at different points in the system and pay for the service through a rate structure made up of multiple components. Each year member agencies advise MWD how much water they anticipate they will need during the next five years. MWD also works with member agencies to develop a forecast of future water demand.

MWD takes a comprehensive and proactive approach to planning for the future. Through coordination with member agencies, MWD has developed regional targets to accommodate growth and face the challenges to supply reliability. Through the past decade, MWD has undertaken several planning initiatives including development and implementation of an Integrated Resources Plan (IRP), a Water Surplus and Drought

Management Plan (WSDMP) and its Strategic Plan and Rate Structure. Together, these programs and plans provide a framework and guidelines for the future.

2. MWD Population and Growth Forecasts

Water demands on MWD are projected according to four key parameters: retail demands, local replenishment demands, local supplies and MWD system storage requirements. To forecast retail demand, MWD utilizes a forecasting system that relates water use to independent variables such as population, housing, employment, income, price, weather and conservation. The demographic and economic variables in the forecast are based on the Southern California Association of Governments (SCAG) 2007 Regional Transportation Plan and the San Diego Association of Government (SANDAG) Series 12: 2050 Regional Growth Forecast (February 2010) forecasts. Figure 4.19.19 (Map of MWD's Service Area), below, for MWD's population and growth estimates presented graphically. The~~se~~ demographic projections from MWD's RUWMP are *from the SCAG and SANDAG reports, which are* supported by environmental impact reports and based on city, county and regional general plans.

3. MWD Water Supply

MWD's water sources consist of the SWP, the Colorado River, *surface and* groundwater, ~~seawater desalination, surface water,~~ water transfers and water conservation projects. Areas of concern regarding each of these types of water sources are discussed above. The wide variety of sources and ~~MWD's~~ continued efforts to create and implement contingency plans and address the ongoing challenges with each of these types of water supplies continues to allow *MWD* to deliver supplies *that* ~~to~~ meet Southern California's growing demands.

As set forth in greater detail below, MWD has concluded, based on the results of its modeling efforts and other analyses, that it can maintain reliable supplies to its member agencies throughout the 2010 to 2030 time period and beyond during all hydrologic conditions. (See MWD 2010 RUWMP, page 12.) MWD's ability to provide this level of water supply certainty is predicated on the regionally developed framework between MWD and its member agencies.

As explained above, MWD provides wholesale treated and untreated water directly to its member agencies which, in turn, provide to their customers a combination of local groundwater, local surface water, recycled water and imported water purchased from MWD. For some member agencies, MWD supplies all the water used within the agency's service area, while others, such as EMWD and WMWD, obtain varying amounts of water from MWD to supplement their local water supply portfolios.

Table 4.19-O: Growth in Occupied Housing In MWD Service Area

	Actual (# of Households)		Interpolated	Projected (# of Households)				
County Within MWD	**2000**	**2005**	**2010**	**2015**	**2020**	**2025**	**2030**	**2035**

According to the statutory relationship between MWD and its member agencies, each year the member agencies advise MWD how much water they anticipate they will need during the next five years. Utilizing this and other demand-related information developed through its MWD-MAIN Water Use Forecasting System, MWD then calculates the demand for the entire region and, based on information regarding existing and proposed local water supply projects, determines the amount of imported, stored, transferred and other water supplies needed to meet projected demands. Consistent with this arrangement, MWD does not provide supply projections to its member agencies.

It is pursuant to this regional and statutory framework that the tables set forth in the 2010 UWMPs prepared by water agencies serving Riverside County, such as EMWD and WMWD, are able to project that water supply and demand will remain in balance during average, single-dry and multiple-dry periods over the next 20-year horizon and beyond. To further implement this framework, MWD member agencies, such as EMWD and WMWD, do not request more imported water supplies from MWD than are necessary to supplement their own expansive efforts to develop local supplies and achieve extraordinary water conservation, particularly during dry and multiple-dry year periods or when imported water supplies may be constrained by regulatory circumstances.

In MWD's RUWMP, Appendix A.1 ("Demand Forecast") discusses the comprehensive approach taken by MWD as part of its demand forecasting. As provided in the RUWMP, MWD considers retail M&I ('municipal and industrial,' a common grouping of water users) demands to represent the full spectrum of urban water use within a region, including residential, commercial, industrial, institutional and unmetered uses. A copy of RUWMP Appendix A.1 is included in Appendix EIR-8 and is also incorporated into this EIR by reference.

According to recent growth forecasts, however, population growth in MWD's service area will average just over 150,000 people per year, increasing from an estimated 18.2 million in 2005 to 22.0 million in 2030. Notably, these new population projections are lower than prior estimates. More conservative projections of employment growth and lowered estimates of future birth rates are partially responsible for the lower growth projections. Another factor is the 2000 Census, which provided population counts 480,000 lower than the best estimates from the California Department of Finance (CDOF) for the six counties encompassed by MWD's service area.

~~To forecast urban water demands, MWD utilizes the "MWD-MAIN Water Use Forecasting System." This system features statistical models that have been adapted to conditions in Southern California and incorporates projections of demographic and economic variables from regional planning agencies (such as SCAG and SANDAG) into statistically estimated water demand models to produce forecasts of water demand. In addition, the MWD-MAIN system features a separate model for each sector. In the residential sector, the forecasts of water demand per dwelling unit are combined with the forecasts of dwelling units from the regional planning agencies to yield an estimate of residential water demand. Similarly, in the nonresidential sector, water use per employee is combined with forecasts of nonresidential water demand. The RUWMP also analyzes population as a key indicator of regional growth. According to the RUWMP (page A.1-3), in the mid-1990s, population growth in MWD's service area slowed during the recession, which disproportionately affected Southern California. During the economic recovery from 1995 to 2000, average population growth rebounded to 230,000 people annually. Since 2000, population within MWD's service area has grown to over 275,000 per year on average, approaching the boom levels of the 1980s.~~

To forecast urban water demands, MWD utilizes the "MWD-MAIN Water Use Forecasting System." This system features statistical models that have been adapted to conditions in Southern California and incorporates projections of demographic and economic variables from regional planning agencies (such as SCAG and SANDAG) into statistically estimated water demand models to produce forecasts of water demand. In addition, the MWD-MAIN system features a separate model for each sector. In the residential sector, the forecasts of water demand per dwelling unit are combined with the forecasts of dwelling units from the regional planning

agencies to yield an estimate of residential water demand. Similarly, in the nonresidential sector, water use per employee is combined with forecasts of nonresidential water demand. The RUWMP also analyzes population as a key indicator of regional growth. According to the RUWMP (page A.1-3), in the mid-1990s, population growth in MWD's service area slowed during the recession, which disproportionately affected Southern California. During the economic recovery from 1995 to 2000, average population growth rebounded to 230,000 people annually. *From 2000-2009, population within MWD's service area has grown by over an average of 205,000 people per year.*

After estimating total projected retail demands, MWD factors in the water saving effects of conservation, including a detailed accounting that distinguishes between code-based conservation (i.e., water saved as a result of changes in water efficiency requirements for plumbing fixtures in plumbing codes), active conservation (i.e., water saved directly as a result of conservation programs by water agencies, including the implementation of best management practices) and price-effect conservation (i.e., water saved by retail customers attributable to the effect of changes in the price of water). After including the effects of conservation on retail demands, the analysis accounts for the use of local supplies available to MWD's member agencies. The analysis then considers the allowance for intermittent interruptions to non-firm, discounted rate supplies sold under MWD's Seasonal Storage Program and the Interim Agricultural Water Program, and estimates firm demands on MWD for single-dry, multiple-dry and average years. (MWD RUWMP, pages II-6 and 7.)

As indicated in their UWMPs, MWD-member agencies that serve water in Riverside County utilize and rely upon the information and analyses derived from MWD's RUWMP as part of their water supply planning and analysis functions, as they are expressly authorized to do by Section 10631(k) of the UWMP Act. As set forth herein, MWD's 2010 RUWMP provides information about MWD water supply reliability and demand calculations. The information set forth in the RUWMP illustrates that MWD will have a reliable water supply available to deliver to its member agencies through 2030 and beyond, even during dry periods mimicking historical patterns.

4. MWD Integrated Resource Planning and Coordination

In its role as the supplemental water supplier to Southern California, MWD faces ongoing challenges in meeting the region's need for reliable, high-quality water supplies. As discussed above, increased environmental regulations and competition for water from outside the region have resulted in changes in delivery patterns and timing of availability of imported water supplies. Because of competing needs and uses associated with these resources, and because of concerns related to regional water operations, MWD has undertaken a number of planning initiatives over the past ten years. MWD's RUWMP discusses and analyzes those efforts.

Particularly important to MWD's mission is its coordinated approach to regional planning through the Integrated Resources Plan (IRP). In the 1990s, several years of drought and regulatory requirements began to affect the reliability of MWD water supply. In response to this challenge, MWD and its member agencies began the IRP process to determine the level of supply reliability needed and to find a cost-effective way to meet the goals established. The IRP was a collective effort drawing input from several groups, including MWD's Board of Directors and an IRP workgroup (comprised of MWD staff, member agency and sub-member agency managers, as well as groundwater basin managers) and representatives from the environmental, agricultural, business and civic communities. It was important that the IRP process be collaborative because its viability was contingent on the success of local projects and local plans in achieving their individual target goals for resource management and development. MWD and member agencies worked together to first gather and analyze data to determine demand and supply alternatives, then to use the information gathered to develop a diverse mix of resources. The outcome

of the IRP process was identification and development of a 'Preferred Resource Mix' which would ensure water supply reliability to MWD and its member agencies.

The IRP was first implemented in 1996 via a plan that ensured MWD and member agencies would meet all full-service demands without interruption through 2020. It set targets for conservation, local supplies, SWP supplies, Colorado River supplies, groundwater banking and water transfers. Using a diverse mix of resources, MWD and its member agencies reduced dependency on any single water supply resource. In 2001, MWD began the process of updating its 1996 IRP to identify changed conditions, make adjustments and extend the planning period to 2025. After extensive cooperation with member agencies and others, the updated plan was adopted in July 2004.

The update addressed several changed conditions and extended reliability projections to 2025. Notable changed conditions listed in the 2003 Update were higher conservation savings, revised goals for SWP and Colorado River supplies, more stringent water quality laws and risk in resource implementation. Two areas of concern noted in the IRP process were the increasingly stringent water quality regulations and the risk associated with implementing planned projects. To manage those and other areas of concern, the IRP Update instituted a planning buffer of up to 10% of regional demands. This supply buffer is developed through increased targets for local supply and an increase of supply from Central Valley transfers. The supply buffer is part of MWD's practice of developing supply at least ten years in advance of need. To evaluate the reliability of the supply, MWD has developed a computer model called, 'IRP-SIM,' which is uses to prepare its overall regional water supply analyses.

MWD uses the IRP-SIM model to evaluate the reliability of its water supplies, including supplies available from the SWP, the Colorado River, water transfers and exchanges, and other sources. The IRPSIM is based on 70 years of historical hydrology (from 1922 to 1991) to allow it to estimate water surplus and shortage conditions over a 20-year period and beyond. The model has enabled MWD to analyze the reliability of deliveries to its member agencies, including those within Riverside County, during normal, worst-case single-year and multiple-year drought events. As mentioned earlier, the results of MWD's modeling indicate that it can maintain reliable supplies under such drought conditions throughout the 2010 to 2030 time period and beyond (MWD RUWMP, page II-15). Detailed analyses regarding MWD's supply projections and IRPSIM modeling are also set forth in Appendix A of MWD's RUWMP, which is incorporated as part of this analysis (see Appendix EIR-8 of this EIR).

As detailed in the analyses, MWD's overall supply and delivery reliability is based not just on SWP and Colorado River supplies, but also on conservation programs, groundwater storage programs and water transfer and exchange programs. Also, MWD's IRPSIM is analogous in some respects to the computer modeling approach utilized by the California DWR to evaluate the overall reliability of SWP supplies in light of the various factors affecting state resources. In the preparation of its SWP Delivery Reliability Report, the DWR also utilizes a model (CALSIM II) to analyze simulated SWP operations according to an 87-year period of historical precipitation and adjusted historical runoff, which are then adjusted to reflect current and future levels of development by analyzing land use patterns and projecting future land and water use. DWR then uses the assembled data to forecast the amount of water available to the SWP under current and future conditions.

In April 1999, MWD also adopted a Water Surplus and Drought Management Plan (WSDM) to provide policy guidance and manage regional water supplies to achieve the reliability goals of the IRP. The WSDM identifies the expected sequence of resource management actions that MWD will execute during surpluses and shortages to minimize the probability of severe shortages and eliminate the possibility of extreme shortages and shortage allocations. Unlike MWD's previous shortage and management plans, the WSDM recognizes the link between surpluses and shortages, and integrates planned operational actions with respect to both conditions.

The guiding principle of the WSDM is to manage MWD's water resources and management programs to maximize management of wet year supplies and minimize adverse impacts of water shortages to retail customers. The WSDM also addresses efficient water use and economical local resource programs, coordinating operations with member agencies to amass as much surplus water as possible available for use in dry years and the pursuit of innovative transfer and banking programs to secure more imported water for use in dry years. Specifically, the WSDM contains the following considerations to govern any equitable allocation of imported water:

- Impact on retail customers and regional economy
- Investments in local resources, including recycling and conservation
- Population growth
- Changes and/or losses in local supplies
- Participation in MWD's non-firm, interruptible programs
- Investment in MWD facilities.

The WSDM distinguishes among surpluses, shortages, severe shortages and extreme shortages. Pursuant to the WSDM, each year MWD evaluates the level of supplies available and existing levels of water in storage to determine the appropriate management stage for that year. Each stage is associated with specific resource management actions designed to avoid extreme shortage scenarios to the maximum extent possible and minimize adverse impacts to retail customers if an extreme shortage occurs.

The sequencing outlined in the WSDM reflects anticipated responses based on detailed modeling of MWD's existing and expected water supply resource mix. When MWD must make net withdrawals from storage to meet demands, it is considered to be in a shortage condition. Under most stages of shortage, MWD is still able to meet all end-use demands for water. For more severe shortage conditions, the WSDM shows that MWD would meet demands by withdrawing water from storage. Under worsening shortage conditions, MWD may undertake additional shortage management steps, including issuing public calls for extraordinary conservation, including the curtailment of Interim Agricultural Water Program deliveries in accordance with their discounted rates, exercising water transfer options or open market water purchases. In an extreme shortage scenario, MWD may be required to implement a plan to allocate available supply fairly and efficiently among its full-service customers and allocations would be based on and enforced through rate surcharges, where member agencies would be required to pay more for deliveries exceeding their respective allotments (MWD RUWMP, pages II-15 and II-16). The benefits of aggressive water conservation and public education efforts are also detailed in MWD's RUWMP (see MWD RUWMP, pages III-5 through III-21).

In total, through effective management of its water supply and implementation of its IRP and WSDM, MWD is able to forecast complete water supply reliability in meeting all non-discounted, non-interruptible demands through the year 2030 and beyond, including all treated/potable supply deliveries to its member agencies in Riverside County.

5. MWD Water Quality

As part of the Integrated Resource Plan, MWD has concentrated on maintaining the quality of source water and developing management programs that protect and enhance water quality. MWD's two largest water supply

sources, the SWP and the Colorado River, each have water quality issues. New standards for contaminants, such as arsenic, and the recognition of the existence of previously unregulated types of contamination, such as perchlorate, may add costs or affect the availability of certain local groundwater storage areas, but the geographically specific nature of these contaminants are not expected to affect the overall availability of MWD supplies. To date, MWD has not identified any water quality issues that cannot be mitigated. Salinity may decrease the amount of water available if membrane treatment is required, with losses of up to 15% of the water processed. Since only a small portion of the total water supply would be treated and it would then be blended with the remaining unprocessed water, there is no significant risk to MWD's water supply availability. The following is a brief summary of major water quality issues associated with water imported from the SWP or Colorado River. See Appendix EIR-8 for additional details.

a. SWP Water Quality

Key water quality issues associated with the SWP include total organic carbon, bromides and salinity. MWD is working to protect the water quality of this source, but has also seen the need for upgraded treatment to deal adequately with water quality concerns. Total organic carbon and bromide levels produce disinfection byproducts that current water treatment plants may be inadequate to fully handle. MWD expects this treatment limitation to be overcome over the next few years as ozone is implemented as the primary disinfectant and does not expect water quality to limit SWP supplies through 2030.

Total Organic Carbon and Bromide: When source water containing high levels of total organic carbon (TOC) and bromide is treated with disinfectants such as chlorine or ozone, disinfection byproducts (DBPs) form. Studies have shown a link between certain cancers and DBP exposure and some studies have also shown an association between reproductive and developmental effects and chlorinated water. In December 1998, the United States Environmental Protection Agency (EPA) adopted more stringent regulations for DBPs and water agencies began complying with those new regulations in January 2002. The EPA promulgated additional DBP rules in January 2006.

Existing levels of total organic carbon (TOC) and bromide in Delta water supplies present significant concern for MWD's ability to maintain safe drinking water supplies and comply with applicable regulations. Levels of these constituents in SWP water increase several fold due to agricultural drainage and seawater intrusion as water moves through the Delta. One of MWD's primary objectives for the CALFED Bay-Delta process is protection and improvement of the water quality of its SWP supplies to ensure compliance with current and future drinking water regulations.

MWD has five treatment plants: two that receive SWP water exclusively and three that receive a blend of SWP and Colorado River Aqueduct (CRA) water. In 2003 and 2005, MWD completed upgrades at its two SWP treatment plants to utilize only ozone as the primary disinfectant. This ozonation process avoids the production of regulated DBPs that would otherwise form in the chlorine treatment of SWP water. The three plants producing blended water meet federal guidelines for these byproducts through managing the blend of SWP and CRA water. The non-ozone plants utilizing blended water also meet federal guidelines through similar blending processes and by limiting the percentage of SWP water used at each plant. MWD has plans, some already in the process of implementation, to install ozonation at all three remaining plants.

Salinity: Water supplies from the SWP have significantly lower TDS concentrations than the Colorado River, averaging 250 mg/L in water supplied through the East Branch. Because of this lower salinity, MWD blends SWP water with high salinity Colorado River water to reduce the overall salinity concentrations of the delivered water. However, both the supply availability and its TDS concentrations can vary significantly in response to hydrologic conditions in the Sacramento-San Joaquin watersheds.

TDS concentrations of SWP water can also vary widely over short periods of time. These variations reflect seasonal and tidal flow patterns, and they pose an additional problem for use of blending as a management tool to lower the higher TDS from the Colorado River supply. For this reason, it may not always be possible to maintain both the salinity objective and water supply reliability unless salinity concentrations of source supplies can be reduced. As discussed above, restrictions on SWP exports due to compliance with FESA and exacerbated by drought conditions has increased MWD's reliance on Colorado River water, affecting MWD's ability to meet its goal of producing water of 500 mg/L TDS at its blend plants.

TDS objectives in Article 19 of the SWP Water Service Contract specify a ten-year average TDS of 220 mg/L and a maximum monthly average of 440 mg/L. These objectives have not been met and Metropolitan is working with DWR and other agencies on programs aimed at reducing salinity in Delta supplies. These programs aim to improve salinity in the San Joaquin River through modifying agricultural drainage and developing comprehensive basin plans. In addition, studies are underway to evaluate if salinity reductions could be obtained by modifying levees in the Franks Tract and other flooded islands (actually levee-enclosed parcels of land generally below water level) in the Delta or by placing operable gates at strategic locations to impede transport of salts from seawater.

Chromium VI: Chromium VI (hexavalent chromium) is a possible contaminant of both groundwater and surface water. Chromium is an inorganic chemical used in electroplating, leather tanning, wood treatment, manufacture of pigments and as a cooling tower treatment for corrosion control. Chromium can enter drinking water sources through discharges from industries, leaching from hazardous waste sites and also erosion of natural deposits. In drinking water, Chromium VI is very stable and soluble. While it is known to cause lung cancer in human when inhaled, the health effects in humans from ingestion are not as well established. The current California maximum contamination level (MCL) for total chromium (which includes Chromium VI) is 0.05 mg/L. There are as yet no specific drinking water standards solely for Chromium VI. However, on August 20, 2009, the California Office of Health Hazard Assessment released a draft public health goal (PHG) of 0.06 µg/L and the Department of Public Health will use this PHG in eventually setting an MCL. Chromium VI levels in SWP water range from 0.03 µg/L to 0.80 µg/L and treated water levels range from 0.03 to 0.70 µg/L.

Nutrients: Elevated levels of nutrients, including phosphorus and nitrogen compounds, can stimulate growth of nuisance algal and aquatic weeds. This can cause taste and odor concerns, as well as impede water flow. SWP supplies have significantly higher nutrient levels than Colorado River supplies and have experienced numerous taste and odor issues in recent years. While current nutrient loads remain a concern and are anticipated to have cost implications, MWD has established a comprehensive monitoring program and response actions to ensure there is no effect on the availability of water supplies.

Arsenic: Arsenic is a naturally occurring element found in rocks, soil, water and air. It can also enter water via runoff from agricultural fields and discharges from industrial processes. Long-term exposure to elevated levels of arsenic in drinking water has been linked to certain cancers, skin pigmentation changes and hyperkeratosis (skin thickening). The federal MCL for arsenic in domestic water supplies was lowered to 10 µg/L as of January 2006 for federal regulations and November 2008 for California regulations. Historically, MWD's water supplies have had low levels of this contaminant, with arsenic levels in SWP water ranging from not detected to 4.0 µg/L, well within the regulatory limits.

Perchlorate: Perchlorate compounds are used as a main component in solid rocket propellant and are also found in some types of munitions and fireworks. Conventional drinking water treatment, including the type of treatment utilized at MWD's treatment plants, is not effective in removing perchlorate. Perchlorate is a concern because it interferes with the thyroid's ability to produce hormones required for normal growth and development. While the EPA is in the process of making its final regulatory determination for the contaminant, the California

Department of Public Health has established a primary drinking water standard for perchlorate with an MCL of 6 µg/L. MWD has not detected perchlorate in SWP water since monitoring began in 1997.

b. Colorado River Water Quality

The most serious threat to Colorado River supplies is salinity levels. Because of its high mineral content (saltiness), Colorado River supplies must be blended (that is, diluted) with SWP water to meet the adopted salinity standards. MWD is working to reduce current salinity levels and prevent them from rising further in the Colorado River. In addition, MWD is also working to protect the Colorado River from uranium, perchlorate and hexavalent chromium. MWD fully expects its source protection efforts to be successful. Therefore, the primary water quality constraint on the use of Colorado River water is salinity levels.

Salinity: Water imported via the Colorado River Aqueduct has the highest level of salinity of all of MWD's sources of supply, averaging around 630 mg/L since 1976. Concern over salinity levels in the Colorado River has existed for many years. To deal with the concern, the International Boundary and Water Commission approved Minute No. 242, "Permanent and Definitive Solution to the International Problem of the Salinity of the Colorado River" in 1973 and a year later President Nixon approved the Colorado River Basin Salinity Control Act.

Salts in the Colorado River system are indigenous and pervasive, mostly resulting from saline sediments in the Colorado River basin that were deposited by prehistoric oceans. They are easily eroded, dissolved and transported into the river system. However, overall salinity control programs have proven very successful and cost-effective, and they have reduced salinity concentrations of Colorado River water by an average of 100 mg/L.

Uranium: A 16-million-ton pile of uranium mine tailings at Moab, Utah, lies approximately 750 feet from the Colorado River. Rainwater has been seeping through the pile and contaminating the local groundwater, which is slowly seeping into the river. There also is the potential for millions of tons of material containing uranium to wash into the Colorado River as a result of a catastrophic flood or other natural disaster. Public perception of drinking water safety is a particular concern with uranium. Remedial actions at the site have been underway for over a decade and the tailings pile has begun to be removed. The entire pile is scheduled to be completely removed no later than 2025. MWD has been monitoring for uranium in the Colorado River Aqueduct and at its treatment plants since 1986. Uranium levels in the Colorado River at MWD's intake range from 1-6 pCi/L, well below California's maximum drinking water standard of 20 pCi/L.

Perchlorate: Perchlorate has been detected at low levels in MWD's Colorado River water supply and in a number of regional groundwater basins. MWD began monitoring for perchlorate in June 1997 when it was detected in the Colorado River and at the Lake Mead outlet of Hoover Dam. It was traced back to the Las Vegas Wash where the source was found to be a chemical manufacturing facility in Henderson, Nevada, which is now undertaking ongoing remediation of the site. As a result of aggressive clean-up efforts, perchlorate levels in Colorado River water at Lake Havasu have decreased significantly in recent years from a peak of 9 µg/L in May 1998 to typically less than 2 µg/L since June 2006. The concentrations of perchlorate in Colorado River water are now less than California's detection limit for reporting purposes of 4 parts per billion (ppb).

Chromium VI: Chromium VI levels in Colorado River water are most often not detected (that is, below 0.03 µg/L), but, when detected, range from 0.03 to 0.08 µg/L.

Nutrients and Other Pollutants: While phosphorous levels are much lower in the Colorado River than the SWP, this nutrient is still of concern. Any addition of phosphorus to Colorado River water can result in increased algal growth and low-nutrient Colorado River water is relied upon by MWD to blend down the higher-nutrient SWP water. Population growth, especially in the Las Vegas area, means high levels of treatment at wastewater

treatment plants will maintain existing phosphorous levels. This will help minimize the operational, financial and public health impacts associated with excessive algal growth and protect downstream drinking water availability.

6. MWD Retail Market Demand

In its 2010 RUWMP, MWD estimates that total retail municipal and industrial (M&I) water use will grow from an annual average of 4.0 million AFY in 2010 to 4.7 million AFY in 2035. Based on its general pattern of future demographic distributions, Riverside County's urban water demand is expected to have an increase of 230,700 AFY between 2010 and 2035. Overall, between 2010 and 2035, single-family residential water use is expected to increase by 17.5%, multi-family water use by 29.4% and a relatively flat trend for estimated non-residential water use in MWD's service area. Between 2010 and 2035, Riverside County's single-family residential demand is expected to increase from 329,000 AFY to 490,000 AFY; multi-family from 54,000 to 86,000 AFY; and nonresidential 47,000 AFY to 69,000 AFY. These numbers assume normal weather conditions and continued water savings due to conservation measures such as tightened plumbing codes, conservation pricing effects and the continuing implementation of utility-funded conservation Best Management Practices (BMPs). These projections likely over-estimates water usage, as they do not include savings derived from SB7x7 (which aims for a 20% reduction).

7. MWD Wholesale to Other Agencies

MWD provides wholesale water service to its 26 member agencies. MWD's two member agencies in Riverside County, Eastern Municipal Water District (EMWD) and Western Municipal Water District (WMWD), both provide wholesale and retail water services in their respective territories, serving approximately 15% of Riverside County by landmass and 71% of Riverside County by population. The water services and issues associated with these member agencies, and their subagencies, are discussed further in the sections that follow, below, as well as in Appendix EIR-8.

8. MWD Other Water Uses

In addition to municipal and industrial uses, MWD also supplies lesser amounts of water for agricultural uses, seawater barriers and groundwater replenishment. Agricultural demand, that is, water use for irrigating crops, is expected to decrease as urbanization continues in Southern California; from 231,000 AFY in 2015 and 186,000 AFY in 2035. Seawater barrier demands, water used to prevent or limit seawater intrusion into the coastal groundwater basins, is expected to remain relatively flat: from 71,000 AFY in 2015 to 72,000 AFY in 2035. Replenishment demand is the amount of water member agencies plan to use to replenish their groundwater basins. This type of water use is also expected to increase between 2015 and 2035, from 177,000 AFY to 191,000 AFY.

Table 4.19-P: MWD Total Retail Municipal and Industrial Demand Forecasts

County	Actual	Projected[2] (Acre-Feet)				
	2010[1]	2015	2020	2025	2030	2035

9. MWD Water Supply Reliability

As demonstrated by the information and analyses in MWD's 2010 RUWMP, the total projected water supplies available to MWD over the next 20 years and beyond are sufficient to meet the total projected demands of its member agencies during normal, single-dry and multiple dry-year periods. See tables below. While both Colorado River and SWP supplies have experienced cutbacks and restrictions, MWD has rights or other access to Colorado River Aqueduct supplies from existing and committed programs, as well as from implementation of the QSA. Colorado River transactions are potentially available to supply additional water up to the Colorado River Aqueduct's capacity of 1.25 million AF on an as-needed basis.

Calculated SWP supplies include incorporation of restrictions on SWP and CVP operations in accordance with the delta smelt and salmonid biological opinions discussed previously, with delivery estimates between 7% (based on the historical single driest year) and 60% (based on the long-term average condition). In dry, below-normal conditions, MWD has worked collaboratively with other contractors to develop numerous voluntary Central Valley storage and transfer programs, with the goal of developing additional dry-year supplies that can be conveyed through available pumping capacity to maximize deliveries through the California Aqueduct during dry hydrologic conditions and regulatory restrictions.

One of the key components of MWD's water supply capability is the amount of water in MWD's storage facilities, because storage is a major component of MWD's dry-year resource management strategy. MWD has both surface storage in Diamond Valley Lake and SWP Terminal Reservoirs, as well as groundwater storage. This stored water is available for use during periods of low surface water supplies as a way of augmenting seasonable and multiyear shortages. See earlier Figure 4.19.10 for major water conveyance infrastructure serving California and Figure 4.19.26 for Colorado River details.

In terms of surface storage, Diamond Valley Lake is Southern California's newest and largest reservoir, its construction nearly doubled the region's surface storage capacity. Having reached capacity in early 2003, Diamond Valley Lake holds up to 810,000 AF, some of which is for dry-year and seasonal storage, with the remainder for emergency storage. MWD received operational control of 218,940 AF in the reservoirs at the southern terminals of the California Aqueduct. Control of this capacity in Castaic Lake and Lake Perris gives Metropolitan greater flexibility in handling supply shortages. Seismic concerns regarding the Perris dam have led to a 50% reduction in the amount of water stored at the lake. Nevertheless, MWD's operational storage has remained the same and MWD has continued to withdraw and replace water from the reservoir.

For groundwater storage, many local programs have been implemented to maximize the use of local water supplies. For many years, flood control agencies within MWD's service area have captured and spread stormwater for groundwater replenishment. To meet its adopted targets for dry year storage, MWD and its member agencies encourage the recharge of the groundwater basins. MWD also implements conjunctive water use through various incentive programs. Storage takes place in one of two ways: direct deliveries to storage, where MWD delivers replenishment water directly to water storage facilities, including spreading sites and injection wells. Or, in-lieu deliveries to storage, where MWD delivers additional water directly to the member agency's distribution system. The member agency then uses this water rather than pumping the groundwater it otherwise would have taken out of storage, leaving water in local storage for future use.

Conjunctive use agreements provide for storage of imported water that can be called for use by MWD during dry, drought or emergency conditions. During a dry period, MWD has the option to call (essentially, release) water stored in the groundwater basins pursuant to its contractual conjunctive use agreements. At the time of the call, the member agency pays MWD the prevailing rate for that water. Since 2007, MWD has drawn on dry-year supply from cyclic storage accounts with several member agencies, long-term replenishment programs and ten contractual conjunctive use storage programs to address shortages from the SWP.

MWD has developed a number of local programs to work with its member agencies to increase storage in groundwater basins. MWD encourages storage through its replenishment, cyclic and conjunctive use storage programs. These programs allow MWD to deliver water into a groundwater basin in advance of agency demands. Discounted replenishment service water is delivered when MWD has surplus imported water supply and is available for use after one year. Cyclic storage agreements allow pre-delivery of surplus imported water for recharge into groundwater basins in excess of an agency's planned and budgeted deliveries. This water can then be purchased at a later time when the agency has need for groundwater replenishment deliveries.

10. MWD Planned Local Water Supply Projects and Programs

As detailed in its 2010 RUWMP, MWD has a number of planned and in-process groundwater water recovery projects, recycled water projects and seawater desalination projects that are scheduled to come online between 2011 and 2025 to provide additional storage and reduce the need for potable water and new water sources. See Tables 4.19-S, 4.19-T and 4.19-U. These groundwater recovery projects include: the Chino Basin 2 and Chino Basin 3 desalters, which have ultimate yields/capacities of 11,760 AF and 10,000 AF, respectively; the Tujunga

Well Treatment and Irvine Ranch Water District Wells 51, 52, 53, 21 and 22, with ultimate yields/capacities of 24,000 AF and 12,700 AF, respectively; and 33 other projects with online dates between 2014 and 2020.

In addition, MWD has planned local recycled water projects that include the Joint Water Pollution Control Plant and the Carbon Canyon/Inland Empire Utilities Agency Regional Recycled Water Distribution System, which will have ultimate yields/capacities of 45,000 AF and 50,000 AF, respectively, as well as more than 80 other recycled water projects scheduled to go online between 2011 and 2020. MWD also has seven seawater desalination projects scheduled to go online between 2012 and 2025. This includes the Huntington Beach Seawater Desalination Project and the Carlsbad Seawater Desalination Project, both scheduled to go online in 2012 and provide with ultimate yields/capacities of 56,000 AF. These investments, in addition to MWD's current supplies, allow MWD to plan for a robust, reliable and flexible water supply that can supply the water needed for the expected growth in the region served by MWD.

Table 4.19-T: MWD Average Year Regional Water Demands

Water Source / Year* (in Acre-Feet)	2015	2020	2025	2030	2035
A. Total Demands[1]					
Retailing Municipal and Industrial (M&I)	4,978,000	5,170,000	5,330,000	5,491,000	5,627,000

E. Firm Demands on Metropolitan[5]	**1,826,000**	**1,660,000**	**1,705,000**	**1,769,000**	**1,826,000**

Footnotes:
All units are acre-feet unless specified otherwise, rounded the nearest thousand. Totals may not sum due to rounding.
1. Growth projections are based on SCAG 2007 RTP and SANDAG Series 12 2050 Regional Growth Forecast (Feb 2010).
2. Includes code-based, price-effect and existing active savings through 2009; does not include future active conservation savings. 1990 is base year.
3. Replenishment Service per MWD Administrative Code Section 4114 includes direct and in-lieu replenishment.
4. IAWP deliveries will be phased out by 2013.
5. Firm demand on MWD equals Full Service demands plus 70% of the interim Agricultural Water Program demands.

Source: MWD, 2009 RUWMP, Table 2-8, page 2-14, 2009.

11. MWD Estimate of Minimum Supply Capabilities

The amount of water that can be delivered by MWD is based on the amount of water available in storage or that can be conveyed, weather conditions and water demands by end users, balanced against the need for both flexibility and reliability. In its RUWMP, MWD calculates water availability for 2015, 2020, 2025, 2030 and 2035 for existing water storage and delivery programs, including in-region storage and programs, the California Aqueduct and the Colorado River Aqueduct, with assumptions for multiple dry-years under hydrologic conditions similar to those of 1990-1992. See Tables 4.19-R, 4.19-S and 4.19-T, as well as the summaries in Tables 4.19-U, 4.19-V and 4.19-W.

Under these assumptions, and even without any of the additional water supply available from programs currently in development and scheduled to be completed within the relevant timeframe, MWD estimates a water surplus of between 12,000 and 237,000 AFY. Under wetter hydrologic conditions and with programs currently under development coming online, MWD estimates potential water surpluses of up to 3,155,000 AFY. See Tables 4.19-U, 4.19-V and 4.19-W. MWD's supplies are considered surplus as long as net annual deliveries can be made to water storage programs.

12. MWD Water Conservation and Best Management Practices (BMPs)

In order to most effectively address potential water shortages, in April 1999 MWD adopted a "Water Surplus and Drought Management Plan" (WSDM Plan). This plan provides guidelines for managing water resources to achieve the reliability goals of the Integrated Regional Plan, as well as the expected sequence of resource management actions that MWD will execute during surpluses and shortages to minimize the probability of severe shortages and reduce the possibility of extreme shortages and shortage allocations. The guiding principle of the WSDM Plan is to manage MWD's water resources and programs to maximize management of supplies in wet years and minimize adverse impacts of water shortages to retail customers. MWD does this, in part, through encouraging efficient water use and economical local resource programs, coordinating with sub-agencies to make surplus water available in dry years, pursuing transfer and banking options, and increasing public awareness about water supply issues. The plan also ensures that if mandatory import water allocations become necessary, they would be calculated on the basis of need, rather than historical purchases, and with consideration to impacts on consumers and the regional economy. Investments in local resources, population growth, local supplies and other specified considerations would also be taken into account to ensure equitable allocation of imported water.

Unlike MWD's previous shortage management plans, the WSDM Plan recognizes the link between surpluses and shortages, and it integrates planned operational actions with respect to both conditions. The WSDM plan defines five surplus management stages to guide the storage of surplus supplies in MWD's storage portfolio and also defines shortage management stages to guide resource management activities based on the amount of shortfall and the water balances in MWD's storage programs. Under almost all shortage conditions, MWD will be able to meet all end-use demands for water. For the most severe water shortages, MWD may undertake additional shortage management steps, including making public calls for extraordinary conservation, curtailing Interim Agricultural Water Program deliveries, exercising water transfer options or purchasing water on the open market. The overriding goal of the WSDM is to never reach the condition of extreme shortage.

Table 4.19-U: MWD Single Dry Year Regional Water Demands

Water Source / Year* (in Acre-Feet)	2015	2020	2025	2030	2035
A. Total Demands[1]

* All units are acre-feet unless specified, rounded the nearest thousand. Totals may not sum due to rounding.

Footnotes:

1. Growth projections are based on SCAG 2007 RTP and SANDAG Series 12 2050 Regional Growth Forecast (Feb 2010).
2. Includes code-based, price-effect and existing active savings through 2009; does not include future active conservation savings. 1990 is base year.
3. Replenishment Service as defined in MWD Administrative Code Section 4114; direct and in-lieu replenishment.
4. IAWP deliveries will be phased out by 2013.
5. Firm demand on MWD equals full service demand + 70% of interim Agricultural Water Program demands.

Source: MWD, 2009 RUWMP, Table 2-6, page 2-12, 2009.

MWD has also adopted a Water Supply Allocation Plan (WSAP) that includes a specific formula for calculating member agency supply allocations and key implementation elements needed for administering an allocation. The WSAP formula seeks to balance the impacts of a shortage at the retail level while maintaining equity on the wholesale level for shortages of MWD supplies of up to 50%. The formula takes into account growth, local investments, changes in supply conditions and demand-hardening aspects of non-potable recycled water use and the results from conservation savings programs.

13. MWD Demand Management Measures

MWD's conservation programs are closely linked to the efforts of the California Urban Water Conservation Council (CUWCC), the organization created to administer the Urban MOU. As a signatory to the Urban MOU, MWD has pledged to make a good faith effort to implement a prescribed set of urban water conservation best management practices (BMPs). MWD also provides technical and financial support to member agencies to help in meeting the terms of the Urban MOU and has submitted its recent demand management (DMM) reports to the CUWCC to comply with RUWMP requirements (see Appendix A.6 of the RUWMP). In addition, MWD's RUWMP also includes discussion of its conservation plans and approach, see Section 3.4 of that document for more information.

a. Regional Conservation Programs

SoCal Water$mart: In July 2008, MWD initiated a new region-wide residential rebate program called, 'SoCal Water$mart.' During its first year of operation, rebate activity exceeded expectations as many residential customers became increasingly aware of the financial incentives available to them to help offset the purchase of water-efficient devices. MWD issued a record 54,000 rebates for residential fixtures totaling $10 million in fiscal year 2008/09, resulting in approximately 2,300 AF of water to be saved annually.

Save Water, Save-A-Buck (Multi-Family): MWD's regional 'Save-A-Buck' program extends rebates to multi-family dwellings. More than 40,000 rebates were issued fiscal year 2008/09 for high-efficiency toilets and washers for multi-family units within Southern California.

Member Agency Residential Programs: In addition to regional programs implemented by MWD, its member and retail agencies also implement local water conservation programs within their respective service areas and receive MWD incentives for qualified retrofits and other water-saving actions. Typical projects include toilet replacements, locally administered clothes washer rebate programs and residential water audits. MWD provides incentives on a variety of water-efficient devices for the residential sector. The following current and past devices contribute to projected conservation savings:

- **High-Efficiency Clothes Washers (HECWs):** MWD has supplemented its HECW rebate using state or federal grants whenever possible. The water efficiency of clothes washers is represented by the 'water factor,' which is a measure of the amount of water used to wash a standard load of laundry. Washers with a lower water factor save more water. MWD has continued to move the market by changing its program requirement to lower water factors. The program eligibility requirement is currently set at water factor 4.0, which saves over 10,000 gallons per year per washer over a conventional top loading washer.

- **High-Efficiency Toilets and Ultra-Low-Flush Toilets:** MWD has provided incentives for toilet programs since 1988. Currently, MWD only provides funding for high-efficiency toilets (1.28 gallons per

flush or less), which use 20% less water than ultra-low-flush toilets (1.6 gallons per flush). Ultra-low-flush toilets are the current standard defined by the plumbing code. MWD uses the EPA-listed WaterSense toilets in its programs as qualifying models.

- **Irrigation Evaluations and Residential Surveys:** MWD provides funding to its member agencies that choose to implement irrigation evaluations and indoor surveys for residents. Irrigation evaluations provide customers with a recommended irrigation schedule and suggested improvements for irrigation systems. Indoor residential surveys provide customers with information on identifying leaks and upgrading water-using devices in the home.

- **Rotating Nozzles for Sprinklers:** Pop-up spray heads with multi-stream, multi-trajectory rotating nozzles represent a new alternative to the irrigation of landscapes. Field tests demonstrate these devices apply water more evenly than traditional nozzles with fixed conical spray patterns, offering the potential for significant water savings. Low precipitation rates associated with these nozzles can reduce run-off and related pollution, thereby offering a substantial value-added benefit when irrigating sloping landscapes.

- **Weather-Based Irrigation Controllers:** Weather-based irrigation controllers (WBICs) are a rapidly evolving conservation technology. Rather than relying on periodic manual adjustments, WBICs adjust irrigation schedules based on rain, temperature, sunlight, soil moisture or a combination of indicators. MWD began funding WBIC incentives in homes after conducting a pilot study that evaluated potential savings and ease of use.

- **Synthetic Turf:** From July 2007 through June 2010, MWD offered an incentive for synthetic turf based on a pilot project conducted with financial assistance from the U.S Bureau of Reclamation. Synthetic turf provides water savings benefits as a replacement for irrigated turf and lawn areas.

b. Commercial, Industrial and Institutional (CII) Programs

CII Save Water, Save-A-Buck Program: The majority of its CII conservation activity comes from MWD's regional Save-A-Buck program. The program had its largest year in fiscal year 2008/09, providing about $8.8 million in rebates for approximately 145,000 device retrofits.

Water Savings Performance Program: This program provides financial incentives for documented water savings for landscape irrigation and industrial process improvements. This program allows large-scale water users to customize conservation projects and receive incentives for five years of water savings for capital water-use efficiency improvements.

Member Agency Commercial Programs: Member and retail agencies also implement local commercial water conservation programs using MWD incentives. Projects target specific commercial sectors, with many programs also receiving assistance from state or federal grant programs. MWD incentives are used as the basis for meeting cost-share requirements.

Public Sector Water Efficiency Partnership Demonstration Program: From August 2007 through 2008, MWD offered a one-time program to provide up-front funding to increase water use efficiency in public buildings and landscapes within its service area through its Public Sector Demonstration Program. The program was designed to reinforce the region's conservation message by demonstrating willingness for public agencies to respond to the call to save water. Participants included various special districts, school districts, state colleges and universities, municipalities, counties and other government agencies. There were four components of the

program: (1) water audits; (2) enhanced incentives; (3) pay-for-performance; and (4) recycled water hook-up. Free water audits were provided and water use experts created an equipment inventory list and made recommendations for replacements or upgrades, with a written report provided as a guide to initiating equipment upgrades. Enhanced incentives were provided to replace high water-use equipment including toilets, urinals and irrigation controllers. Program incentives were often sufficient to cover the total cost of the equipment. Pay-for-performance incentives were also offered to reduce landscape irrigation water use by at least 10% through behavioral modifications. The CII programs provide rebates for water-saving plumbing fixtures, landscaping equipment, food-service equipment, cleaning equipment, HVAC (heating, ventilating, air conditioning) and medical equipment.

c. Research and Development Programs

The Innovative Conservation Program provides funding to individuals and organizations to test new technologies. The Enhanced Conservation Program provides funding directly to MWD's member agencies to encourage new and creative approaches to implement urban water conservation.

d. Water Conservation Ordinances

In June 2008, MWD adopted a Water Supply Alert resolution following Governor Arnold Schwarzenegger's proclamation of a statewide drought. Among other provisions, the alert encouraged cities, counties and local public water agencies to adopt and enforce local water conservation ordinances. To facilitate ordinance adoption, MWD compiled a library of available local ordinances, developed a model water conservation ordinance and hosted several workshops. As a result, approximately half of the 19 million residents in MWD's service area are now covered by adopted ordinances and an additional one-third reside in jurisdictions that have taken action toward adoption of ordinances.

e. New Construction Programs

With grants from the USBR and the State of California, MWD offered financial incentives through the California Friendly® New Home Program. Through it, builders of new single-family model homes and multi-family developments are encouraged to incorporate water-efficient fixtures and landscapes, including high-efficiency toilets and clothes washers, smart irrigation controllers and landscapes designed with appropriate plant palettes and efficient irrigation systems. California Friendly® model homes showcase residential water efficiency, helping to increase consumer awareness of water-conserving features and provide inspiration for water-conserving landscapes. Since program inception in 2003, MWD has provided incentives to eight homebuilders for more than 220 new homes with over 300,000 square feet of landscape.

f. Conservation Funding

MWD's Conservation Credits Program (CCP) provides financial incentives and funding for urban BMPs and other demand management-related activities. Established in 1988, this funding mechanism supports MWD's commitment to conservation as a long-term water management strategy. Project proposals must: have demonstrable water savings; reduce water demands on MWD's system; be technically sound; and require MWD's participation to make the project financially and economically feasible. Additional funding for conservation programs has been made available through government agencies. MWD has worked to obtain a share of this funding to enhance the region's water conservation investments.

g. Measurement and Evaluation

MWD staff have served as technical advisors for a number of state and national studies involving the quantification and valuation of water savings for the purposes of: providing a means to measure and evaluate the effectiveness of current and potential conservation programs; developing reliable estimates of various conservation programs and assessing the relative benefits and costs of these interventions; providing technical assistance and support to member agencies in the areas of research methods, statistics and program evaluation; and documenting the results and the effectiveness of MWD-assisted conservation efforts.

h. Other Conservation

MWD has conducted annual advertising, education and community outreach campaigns since 2003 under its bewaterwise.com® and California Friendly® brands to urge Southern California consumers and business owners to make permanent changes in their everyday uses of water. From 2007 through 2010, MWD's Board of Directors authorized an expansion of these efforts in order to meet the critical water supply crisis facing the state. Outreach campaigns in the latter part of the decade reflected these unprecedented challenges with more urgent calls for water conservation behavior. Creative ads, such as "Time to Get Serious" and "Cut Your Water Use," were seen and heard across more media outlets at higher frequency levels and over longer periods than pre-2007 campaigns. MWD was also a lead sponsor of the "California's Water: A Crisis We Can't Ignore" statewide campaign with the Association of California Water Agencies in fall 2007. Leading up to the summer of 2009, MWD's "Move the Needle" outreach campaign (featuring a water supply gauge nearing empty) communicated the change from voluntary to mandatory water conservation in many Southern California cities and communities. MWD's California Friendly® Landscape Training Program offers courses in irrigation efficiency and water-wise garden design. Nearly 9,000 landscape maintenance professionals and residents attended the workshops in 2008-2009 in English and Spanish.

14. MWD Recycled Water

In the 1990s, the U.S. Bureau of Reclamation (USBR), in cooperation with MWD, DWR and six other Southern California water agencies, studied the feasibility of regional water reclamation projects in Southern California and identified 34 potential regional projects within MWD's service area with an estimated yield of 450,000 AF per year. MWD and its member agencies continue to explore these and other projects and to develop updated plans on a regular basis. MWD has identified a potential for more than 1.0 million AF of recycled water to be developed by 2050. The majority of these projects are currently in conceptual planning phases. There are about 335,000 AF per year of planned and permitted uses of recycled water throughout MWD's service area. These include landscape irrigation, commercial and industrial use, seawater intrusion barriers and groundwater recharge applications. It is anticipated that about 458,000 AF per year of new recycled water could be developed in MWD's service area by the year 2035. A number of these projects are currently being implemented and will go on-line within the next five years. Other projects are in various stages of planning and their development will depend on cost, financing, regulatory actions and water supply demands.

15. MWD Conclusion

The 2010 RUWMP demonstrates that MWD has supply capabilities that will be sufficient to meet expected demands from 2010 through 2035 under normal, single dry-year and multiple dry-year conditions. MWD has comprehensive plans for handling up to a 50% reduction in its available water supplies and catastrophic water interruptions in its Water Surplus Plan and its Drought Management and Water Supply Allocation Plans. MWD also has an emergency storage requirement to mitigate against potential interruption in water supplies resulting

from a catastrophe in Southern California, including a seismic event along the San Andreas Fault. In addition, MWD is working with the State of California to implement a comprehensive improvement plan to address catastrophic occurrences outside of Southern California, such as a large seismic event hitting the Delta and causing levee failure and SWP delivery disruption. MWD has plans for supply implementation and continued development of a diversified resource mix including programs in the CRA, SWP, Central Valley transfers, local resource projects and in-region storage which together enable the region to meet its water supply needs and continue to enable a surplus to prepare for future dry years.

Based on the 2010 RUWMP, MWD's overall water demand will total 2.0 million AF in 2015 and increase to 2.1 million AF by 2035. Based on existing supply capabilities, MWD has determined that it can meet 100% of its member agencies' projected supplemental demands over that period for average, single-dry and multiple dry-year scenarios. With the addition of all water supplies that are under development, MWD will further increase its reserve supplies. Additionally, MWD finds in its 2010 RUWMP that there are no water quality issues that would insurmountably affect water supply.

F. Local Water Providers in Western Riverside County

As mentioned previously, in western Riverside County, MWD serves the two major wholesalers (EMWD and WMWD) that serve the region. Another State Water Contractor, San Bernardino Valley Municipal Water District (SBVMWD), also provides SWP water to retailers in Riverside County: West Valley Water District, Yucaipa Water District and the City of Riverside. Though located in San Bernardino County, SBVMWD is included in this EIR since it serves Riverside County providers and utilizes (or affects) groundwater basins used by Riverside County providers. The three major providers are discussed in brief below, along with notes on the retail providers they serve. Additional information on each may also be found in Appendix EIR-8.

In western Riverside County, all of the local retail providers rely at least in part on imported water except for the Jurupa and the Rubidoux Community Services Districts in northwestern-most Riverside County. These two providers are described separately in the section discussing local water providers that rely on groundwater only, later in this chapter.

1. Eastern Municipal Water District

Eastern Municipal Water District (EMWD), a public water agency, was formed in 1950 and annexed into MWD a year later. As one of MWD's 26 member-agencies, it receives imported water supplies from both Northern California via the SWP and from the Colorado River Aqueduct (CRA) and provides wholesale water to six sub-agencies of its own, as well as to its own retail customers. See Figure 4.19.20 (Map of EMWD's Service Area). EMWD's 2010 Urban Water Management Plan (UWMP) covers a variety of issues related to water supply, demand and reliability. Additional information about this water district is provided in Appendix EIR-8.

a. Notes on EMWD

EMWD has four existing sources of water supply: imported MWD water, recycled water, local groundwater and desalted groundwater. Imported water (from MWD) is either delivered directly as potable water, delivered as raw water and treated at EMWD's two local filtration plants, or delivered as raw water for non-potable use. For the past six years, imported water has remained proportionally consistent or decreased, even as EMWD added over 20,000 new water connections, through constructing desalination facilities, increasing recycled water use and improving water efficiency, all which have also increased supply reliability.

EASTERN MUNICIPAL WATER DISTRICT SERVICE AREA

This page intentionally left blank.

The majority of EMWD's current and projected water supplies are imported through the MWD. Potable imported water is delivered directly from MWD's two large filtration plants and then EMWD's microfiltration plants in Hemet and Perris remove particulate contaminants to achieve the applicable potable water standards. Untreated water from MWD is also percolated into groundwater in the eastern service area, used for agricultural purposes in the northeast and in the south by RCWD. Recycled, highly treated wastewater is also used for many purposes including agriculture, landscape irrigation and industrial use through an intricate web of pipelines from EMWD's four Regional Water Reclamation Facilities as well as several storage ponds.

Table 4.19-AB: Eastern Municipal Water District Background Information

Sub-Agencies Served[1]			**Cities and Communities Served[2]**		
City of Hemet Water Department			City of Hemet		Lakeview

Footnotes:
1. Unless noted otherwise, the District provides wholesale water to these sub-agencies.
2. City/community may be served by this district either wholly or partially. Areas in which only a small fragment are served by the water district or are outside of the district's formal service area may be omitted for clarity.
3. Services and service area statistics from Riverside LAFCO, 2005 Water and Wastewater Municipal Service Review.
4. Only facilities operated directly by the listed water agency included.
5. EMWD provides non-potable agricultural water. For LHMWD, EMWD only supplies non-potable water.
6. EMWD provides emergency back-up service only.

Source: EMWD, UWMP, 2010. Riverside LAFCO, Water and Wastewater Municipal Service Review Report, 2005.

The Hemet/San Jacinto area contains good quality water and is a major source of municipal as well as private production, although water levels are in serious decline. The groundwater used by EMWD comes from wells located mostly within the San Jacinto watershed and serving the northern portion of EMWD's service area. EMWD produces potable groundwater from two areas within the San Jacinto watershed, each covered by a management plan: the West San Jacinto (WSJ) Groundwater Basin Management Plan area and the Hemet/San Jacinto (HSJ) Water Management Plan area. The WSJ area is subject to an existing groundwater management plan. In the Hemet/San Jacinto Plan area, EMWD's groundwater production is currently constrained by the 1954 Fruitvale Judgment and Decree. See Appendix EIR-8 for additional details on Fruitvale and other water rights issues. In accordance with the Judgment and Decree, the Hemet/San Jacinto Water Management Plan was completed in 2011 in order to ensure the safe, productive use of the basin.

3. Recycled water system plus desalter output.

Source: Eastern Municipal Water District, Urban Water Management Plan, 2010.

Since the area's native potable groundwater production is limited, or will be limited according to management plan provisions, to prevent continued overdraft, EMWD developed alternatives to assure reliability. Pursuant to its Integrated Recharge and Recovery Program (IRRP), filtration plants treat and deliver imported water to areas previously dependent on groundwater, and recycled water is provided for landscape and agriculture irrigation. Portions of EMWD also overlay the Santa Margarita watershed, but EMWD does not extract groundwater from it and states it has no plans to do so. Two EMWD desalination plants also convert brackish groundwater into potable water in the Sun City area and support EMWD's groundwater salinity management program.

b. EMWD Water Availability

According to EMWD's 2010 UWMP, plans are in place to recharge local groundwater with imported or recycled water and to desalinate groundwater to reduce import demands and provide a sustainable supply. The basins' Water Management Plans limit the amount of water being extracted from the basins to a sustainable yield and the continued recharge of the Hemet/San Jacinto basin using imported water pursuant to the IRRP will ensure that

basin overdraft is eliminated and avoided in the future. Planned local supplies will supplement imported supplies and improve reliability for EMWD and the region.

EMWD also aggressively promotes efficiency through implementation of local ordinances, conservation programs and a tiered pricing structure to reduced retail account demands. Reducing demand allows existing and proposed water supplies to stretch farther and reduces the potential for water supply shortage. Because EWMD also expects water efficiency savings from future recycled water, desalination and planned additional conserved water transfers/exchanges, the district also has a potential surplus which could offset future growth in excess of that planned, if necessary, or buffer against imported water supply variability, SWP water in particular. Altogether, for these reasons, EMWD has concluded that it has the ability to meet current and projected water demands through 2035 during normal, historic single-dry and historic multiple-dry years using existing supplies and imported water from MWD with existing supply resources.

c. EMWD Sewer and Wastewater Services

As noted above, EMWD is one of Riverside County's largest providers of wastewater treatment services. Its 2010 UWMP (page 51) notes that EMWD is responsible for all wastewater collection and treatment within its service area. It has four operational regional water reclamation facilities (RWRF) located throughout EMWD (i.e., Moreno Valley, Perris Valley, San Jacinto and Temecula Valley) and in 2010 treated 46,500 AFY of wastewater. All off EMWD's RWRFs produce tertiary effluent suitable for DHS-permitted uses, including irrigation of food crops and full-body contact recreation. In addition to treatment facilities, EMWD has several recycled water storage ponds. These ponds permit EMWD to sell more than just the recycled water produced by its plants during peak demand months (i.e., June – September). Additionally, storage in these unlined surface impoundments facilitates extensive groundwater recharge. When storage capacity is full, surplus recycled water is disposed of through a regional outfall pipeline to Temecula Creek and the Santa Ana River. Thus, in all, the recycled water produced by EMWD is disposed of via a combination of customer sales (up to 32,500 AF sold annually, mainly for agricultural use), discharge to Temecula Creek and percolation and evaporation from EMWD storage ponds. Among its customers, EMWD sells recycled water to the CDFW for environmental use within the San Jacinto Wildlife Area.

d. EMWD Subagencies

As listed in Table 4.19-AB, above, EMWD supplies wholesale water to a number of subagencies: Lake Hemet Municipal Water District, Rancho California Water District and Elsinore Valley Municipal Water District, as well as the cities of Hemet, San Jacinto and Perris, plus assorted water companies and other private providers. Of these providers, all except the City of Perris use locally obtained groundwater in addition to imports from EMWD. Two also have access to surface water: Lake Hemet MWD uses water from the San Jacinto River and Elsinore Valley MWD uses water from Canyon Lake. Two districts (Elsinore Valley and Rancho California) also obtain water from Western Municipal Water District. Although EMWD has found its water supplies, including its imports, to be sufficient, this finding may or may not hold for individual local agencies which themselves may rely on local supplies other than imports. These local sub-agency providers are summarized below.

Elsinore Valley Municipal Water District: EVMWD provides public water service, wastewater treatment, disposal and recycling for over 35,000 service connections. According to Riverside County LAFCO (2005), EVMWD serves a 97-square mile service area that includes the cities of Lake Elsinore, Canyon Lake and Murrieta, as well as several unincorporated communities. See Figure 4.19.22 (EWD/EVMWD Map). The water EVMWD provides is a blend of local groundwater, imported water from WMWD and surface water from Railroad Canyon Reservoir (Canyon Lake). EVMWD imports treated water from MWD's Skinner and Mills

Water Treatment Plants, located in Temecula and Riverside, respectively. Since 2005, LAFCO reports that approximately 51% of EVMWD's water supply is imported.

For local groundwater supplies, EVMWD has access to groundwater from several area basins, including the Elsinore, Temescal Valley, San Bernardino Bunker Hill, Rialto-Colton, Riverside-North and Coldwater Basins, with the primary source of EVMWD's groundwater supplies the Elsinore Groundwater Basin. See Section 4.19.6.L for a description of this basin. EVMWD pumps approximately 94% of the groundwater produced by that basin (approximately 13.7 mgd) from its nine wells. Elsinore Water District (EWD) has the capacity to pump 5% of the basin's groundwater production. However, currently EVMWD supplies potable water to meet EWD's demands and EWD does not pump any groundwater. EVMWD also pumps groundwater from the Coldwater, Lee Lake and Bedford Basins in Temescal Valley for both potable and non-potable uses.

While EVMWD's wells have a total pumping capacity of 2,274 AFY, based on past pumping rates, EVMWD's share of the safe yield is only 1,250 AFY, limiting the projected supply from Temescal Valley to that amount. Total potable water supply from all sources has averaged 28,500 AFY, with relatively stable groundwater production of 14,000 AFY. In response to continued population growth, additional water has been imported from MWD via EMWD or WMWD when needed. Imported water purchases have averaged 9,600 AFY. Per EVMWD's 2010 UWMP, its water supply from all sources is predicted to be fully reliable through 2030. Further, even if more water were needed than is currently predicted, EVMWD also has to ability to purchase additional raw or treated water from MWD. EVMWD also operates three wastewater treatment plants with a total capacity of 9.7 MGD (as of 2005 per LAFCO).

Lake Hemet Municipal Water District: LHMWD provides retail potable water, irrigation water and sewer collection services to residents of Hemet and San Jacinto, as well as Garner Valley and surrounding unincorporated areas. It does not provide wastewater treatment services; collected sewage is treated by EMWD. There are approximately 13,600 domestic and 50 agricultural customers within LHMWD's 26-square mile service area according to LAFCO.

LHMWD currently serves its water customers from three main sources of supply: locally pumped groundwater, surface water from the San Jacinto River system and water purchases from EMWD. Local groundwater from the Hemet and San Jacinto groundwater basins is the primary potable water source. It has generally been acknowledged by the district, EMWD, the cities of Hemet and San Jacinto and the local agricultural community that the San Jacinto and Hemet Groundwater basins are currently in a state of overdraft, with total groundwater extractions by local agencies and private groundwater users exceeding the natural long term recharge capability of the groundwater basins. LHMWD operates seven wells that provide water to the domestic water system and six wells that supply water to the irrigation system. The district also leases private wells to supplement its domestic and irrigation water needs during high demand periods.

Surface water from the San Jacinto River system averages 3,600 AFY, which is approximately 20% of LHMWD's total water supply. Most of the surface water is used for agricultural purposes, but a portion is conveyed to the LHMWD's Eggen Water Treatment Plant for treatment prior to domestic use. The district can also purchase water from EMWD. LHMWD is entitled to a maximum of 336 AFY of EMWD's Fruitvale System water at a special rate and can purchase additional surplus groundwater as needed at EMWD's normal billing rate.

LHMWD will need additional water supplies to be able to satisfy projected growth within the District's service area. The district has committed to working with EMWD, the cities of Hemet and San Jacinto and the DWR to develop a comprehensive Regional Groundwater Management Plan to secure sufficient groundwater supplies based on appropriate safe yields. Supplemental future water supply options include a recycled water distribution system supplied from the EMWD, supplemental imported water supplies, increased use of local surface water and

demand reduction/conservation. By relying more on local surface water and recycled water, LHMWD will be able to cut its reliance on groundwater from 70% of total supply in 2004 to 59% of total supply in 2025.

Rancho California Water District: For historic reasons, this district receives water from both EMWD and WMWD. See full discussion under WMWD, in the subsequent section, below.

2. Western Municipal Water District

As detailed in its 2010 UWMP Update (dated June 2011), the Western Municipal Water District (WMWD) was formed by the voters in 1954 and is a member of MWD. It receives both Colorado River and SWP water from MWD, and also uses local groundwater from desalters. WMWD provides wholesale water to 14 other water providers, either directly or indirectly, as well as its own retail customers. Additional information about this water district is provided in Appendix EIR-8.

a. Notes on WMWD

WMWD's retail water uses include residential, commercial, industrial, institutional, governmental, landscape and agricultural. In its wholesale area, most of the water purveyors in the WMWD service area utilize local sources (groundwater, recycled water and a minor amount of surface water), along with imported water and desalter water purchased from EMWD to meet water demands. Total water demand within WMWD's retail area has been increasing since 1995, with demands nearly tripling between 1995 and 2010, although agricultural demand has continued to drop. By year 2035 forecasted demand will increase by approximately 90%. At build out (around 2040), WMWD predicts its total water demands to be nearly double current levels.

WMWD relies on imported water, local groundwater and recycled water to meet its wholesale and retail demands. The District obtains approximately 90% of its total supply through imported water sources from MWD. About one-quarter of the water WMWD purchases from MWD comes from the Colorado River Aqueduct and about 75% from the SWP. WMWD also purchases non-potable water from Elsinore Valley Municipal Water District (Meeks and Daley Water Company purchase) and, when available, from the City of Riverside.

As shown in Figure 4.19.21 (WMWD Service Area), WMWD's local supplies come from groundwater in the Riverside-Arlington, San Bernardino Basin Area (SBBA) and Murrieta basins, as well as from WMWD's own Water Recycling Facility. Future supplies will be developed locally in the Perris North, Arlington and Chino basins, as well as through expansion of WMWD's water recycling facilities.

WMWD intends to utilize excess water, when available, and store this water in the SBBA. This water will come from two different projects – Santa Ana River water rights and the Riverside Corona Feeder. This water would be extracted as needed and transported to WMWD's customers and other water purveyors within WMWD's boundaries for use during dry years. Currently WMWD has 6,000 AF of banked groundwater. Modeling indicates conservatively that WMWD could have 15,000 AF of water banked in most years. This banked water would only be used when needed during drought or water shortage periods.

The Riverside Corona Feeder is a planned regional conveyance facility, comprised of up to 20 wells and 28 miles of pipeline capable of moving up to 40,000 acre-feet per year of groundwater previously banked in the SBBA. The Riverside-Corona Feeder will originate in the SBBA area in San Bernardino County (near the southern portion of the City of San Bernardino) and extend southwesterly to the City of Corona. The Riverside-Corona Feeder will make it possible for WMWD to store excess stormwater, excess SWP water and Santa Ana River water in the SBBA.

b. WMWD Water Availability

While increasing conflicts over the quality and quantity of imported water from the SWP and CRA have lead to increasing imported water costs, WMWD continues to rely on MWD's 2010 RUWMP to evaluate the dependability of these supplies and the amount of imported water that will be available in the WMWD service area. The imported water supply is highly reliable for WMWD, with the full supply available in normal, single-dry years and multiple-dry years.

Table 4.19-AE: Western Municipal Water District Background Information

Sub-Agencies Served[1, 5]	Cities and Communities Served[2]
City of Corona (Department of Water and Power)	City of Murrieta
City of Norco Water Department	City of Riverside
City of Riverside Water Department	Gavilan Hills
Box Springs Mutual Water Company	Lake Hills
Eagle Valley Mutual Water Company	Lake Matthews
Elsinore Water District (EWD)	Mission Grove
Elsinore Valley Municipal Water District (EVMWD)	Orangecrest
Home Gardens County Water District	Victoria Grove
Jurupa Community Services District (JCSD)[6]	Woodcrest
Lee Lake Water District (LLWD)	
Rancho California Water District (RCWD)	
Riverside Highland Water Company	
Rubidoux Community Services District (RSCD)	

Service Area Statistics[3]			
Size	326,400 acres	***CA Hydrologic Region***	South Coast
Population	657,400 people	***Regional WQCB***	8 – Santa Ana

Services Provided[3]					
Distribution	X	Wholesale Water	***Operations[4]***	X	Potable Water Treatment
	X	Retail Water		_	Desalination
	X	Recycled or Non-Pot. Water		_	Groundwater Recharge
	X	Wastewater (Collection)		X	Wastewater Treatment

Footnotes:
1. Unless noted otherwise, the District provides wholesale water to these sub-agencies.
2. City/community may be served by this district either wholly or partially. Areas with only a small fragment served by the water district or outside of the district's formal service area may be omitted for clarity.
3. Services and service area statistics from Riverside LAFCO's 2005 Municipal Service Review.
4. Only facilities operated directly by the listed water agency included.
5. In 2005, WMWD absorbed the Murrieta County Water District into its operations.
6. JCSD includes the Santa Ana River Water Company. JCSD receives water through the cities of Corona and Norco; it does not purchase water directly from WMWD. It also gets water from EMWD as well.

Source: WMWD, UWMP, 2010. Riverside LAFCO, Water and Wastewater Municipal Service Review, 2005.

Local groundwater and other water purchased through agreements are deemed reliable in single-dry and multiple-dry years, except for the Temecula-Murrieta Basin supply, for which long-term records are not available. To be conservative, WMWD assumes a 15% reduction in water availability for this service area in dry years. Also, the District assumes conservation reductions will occur slowly, in order to avoid over-estimating potential water savings. WMWD's planned future supplies include new groundwater production and expanded recycled water use. Future supplies will be developed locally, in the Perris North, Arlington and Chino basins, as well as through expansion of the Western Water recycling facility and the Arlington desalter facility.

1. All data from UWMP, unless noted otherwise. All data rounded to nearest hundred
2. Water years used (for average, dry and multi-year dry benchmarks): 2004-2009, 1977 and 1990-1992.
3. Recycled water system plus desalter output.
4. "Build out" year according to WMWD 2010 UWMP.

Source: Western Municipal Water District, Urban Water Management Plan, 2010.

In regard to its own water reliability calculations, WMWD evaluated its ability to supply water to meet expected demands over the 25-year planning period during an average/normal year, single-dry year and multiple-dry years. As shown in Table 4.19-AG, under all three scenarios WMWD expects to have water surpluses, even under the most extreme multiple-dry year scenario.

It is for these reasons that WMWD has concluded that the combination of imported water and expanded local resource programs would ensure that these supplies can be met in the future. As discussed above regarding specific water sources, local groundwater and other water purchased through agreements are considered 100% reliable in single-dry or multiple dry years, except for the Temecula-Murrieta Basin supply. WMWD has only been pumping water from the Temecula-Murrieta Basin since late 2005 and does not have long-term records on water available from this source. Thus, to be conservative, until more data is available, WMWD is assuming its use of Temecula-Murrieta Basin water could be reduced by 15% in a single-dry or multiple dry years. However, even with this conservative estimate, between 2015 and 2040 WMWD has surplus water supplies available each

year between 56,000 and 95,000 AFY, depending on the type of water year. This demonstrates that WMWD has sufficient water supplies to fully supply all potential and planned growth.

c. WMWD Sewer and Wastewater Treatment Services

According to its 2010 UWMP (page 4-1), WMWD operates two wastewater treatment plants that service its Riverside retail service area. That area is also served by the City of Riverside's Riverside Water Quality Control Plant and scattered individual septic systems. The two WMWD are the Western Riverside County Regional Wastewater Treatment Plant (WRCRWTP) and the Western Water Recycling Facility (WWRF), which was formerly the March Wastewater Treatment Plant. Wastewater treatment in WMWD's other retail areas is provided by EMWD at its Temecula Valley Regional Water Reclamation Facility (TVRWRF) and by RCWD at its Santa Rosa Water Reclamation Facility (SRWRF).

WMWD's regional plant (WRCRWTP) provides tertiary treatment with the resulting reclaimed water available for reuse or for discharge through an outfall to the Santa Ana River. Its current capacity is 8 mgd, with an expansion capacity of 32 mgd total. This facility also processes wastewater from Norco, JCSD and the Home Gardens Sanitary District. As of December 2010, average flow into the plant was 6.6 mgd. Discharges to the Santa Ana River are typically 5,000 AFY, although the City of Norco was set to purchase just under 900 AFY of the recycled water once conveyance facilities from the plant were completed. WMWD's other plant, the WWRF, treats domestic wastewater from the March Air Reserve Base and the north-central portion of the district's Riverside service area. As of 2010, the plant produced approximately 1,000 AFY of secondary treated water, which is discharged to an impoundment and then pumped to supply recycled water to the Riverside National Cemetery and a golf course (approximately 800 AFY). When the supply exceeds storage capacity, it is conveyed to the WRCRWTP for tertiary treatment and then discharged to the Santa Ana River.

d. WMWD Subagencies

As reported in their 2010 UWMP Update (page 1-14), WMWD serves nine water purveyors with both treated and raw water using Colorado River and SWP supplies transported by MWD, and also treated water from the Arlington desalter. In addition to water purchased from WMWD, most of these water purveyors also pump and deliver local groundwater and/or recycled water within their respective service areas. None use surface water. It should also be noted that, although WMWD has found its water supplies, including its imports, to be sufficient, this finding may or may not hold for individual local agencies which themselves may rely on local supplies other than imports.

(1) MWD Member Agencies and Customers

WMWD's "member agencies" and customers are listed in Table 4.19-AE, above, and outlined briefly below. Water districts supplied with wholesale water by WMWD include: Elsinore Water District, Elsinore Valley Municipal Water District, Lee Lake Water District and Rancho California Water District, as well as the cities of Corona, Norco and Riverside, plus assorted water companies and other private providers.

Elsinore Valley Municipal Water District: This district receives water from both WMWD and EMWD. Elsinore Valley Municipal Water District (EVMWD) serves approximately 40,000 customers in a 96-square-mile service area in the Lake Elsinore region. EVMWD's water supply is a blend of local groundwater, surface water from Canyon Lake, which EVMWD owns, and imported water. Canyon Lake impounds local runoff from the 750-square-mile San Jacinto River watershed. The lake holds nearly 12,000 AF of water behind Railroad Canyon Dam. See Figure 4.19.22.

EVMWD imports treated water from the Skinner and Mills Water Treatment Plants (WTPs), located in Temecula and Riverside, respectively. Both treatment facilities are owned and operated by MWD. Since 2005, approximately 61% of EVMWD's supply has been imported. In 2009, EVMWD, purchased 16,500 AF from WMWD. See discussion under EMWD, above, for additional details on this water district.

Lee Lake Water District: In the foothills of the Cleveland National Forest, Lee Lake Water District (LLWD) provides potable and reclaimed water to residents of the Temescal Valley. The district has approximately 2,000 service connections across a service area of approximately 450 acres (though its total service area span roughly 6,755 acres). It also provides wastewater collection, treatment and disposal for area residents.

The main portion of Lee Lake Water District is served with imported water from WMWD. LLWD obtains most of its potable water from MWD, which imports it from Northern California via the SWP. The water is then treated at the Henry J. Mills Water Filtration Plant in Riverside and delivered to LLWD via the Mills Pipeline. Other portions within the Lee Lake Water District boundary are either undeveloped, supplied from wells, or supplied from the City of Corona or the EVMWD. LLWD purchased about 3,100 AF of water from WMWD in 2009. Since LLWD's formation, Temescal Valley has undergone much growth as citrus cropland has given way to numerous residential communities, businesses and industrial parks. (WMWD UWMP, 2010.)

LLWD also owns and operates three wastewater treatment facilities. The California Meadows, Butterfield Estates and the Lee Lake Water Reclamation Facility perform wastewater treatment duties for wastewater produced within the District. The most recent addition, the Lee Lake Water Reclamation Facility, is capable of treating 1.5 million gallons per day of raw sewage and producing reclaimed water usable for landscape irrigation and other non-consumptive purposes. Lee Lake also provides incentives for conservation through a tiered rate structure based on the amount of usage. Lee Lake tests water quality three times per month for microbiological organisms and once annually for all other constituents as required by federal and state regulations. Low levels of color and turbidity are a significant factor in customer satisfaction and LLWD delivers the clearest water possible to every household. LLWD water averages a TDS level of 261mg/L.

Rancho California Water District: *RCWD is a "Special District" organized and operated pursuant to the California Water Code. It is governed by a seven-member board of directors that is elected by the voters of the region. RCWD is not a member agency of MWD, but rather contracts through EMWD and WMWD (which are member agencies) for its imported water supplies.* RCWD serves ~~approximately 120,000 customers~~ *134,000 customers with 44,000 service connections (per RCWD's letter to the County dated June 30, 2014)* within a service area that encompasses nearly 100,000 acres *(approximately 156 square miles)* in southern Riverside County. RCWD is divided into the Rancho Division, served by EMWD, and the Santa Rosa Division, which is served by WMWD. ~~The District has 940 miles of water mains, 36 storage reservoirs, one surface reservoir (Lake Vail) and 47 groundwater wells. In 2009, WMWD delivered approximately 22,000 AF of water to RCWD.~~ *In their letter to the County (dated June 30, 2014) RCWD reports that its capital asset value is approximately $518 million with 962 miles of water mains, 43 storage tanks, one surface reservoir (Vail Lake) and 53 groundwater wells. RCWD delivers a combination of local groundwater, recycled water and imported water to meet domestic, industrial and agricultural demands. As of June 2014, these demands total an average of 63,000 AFY of potable water, which is 63% of their projected buildout demand. The existing non-potable/recycled water demand is currently (as of June 2014) totaling an average of 3,800 AFY. RCWD projects buildout potable water demand is to be approximately 101,000 AFY (per their letter dated June 30, 2014).*

~~RCWD is implementing water management strategies to address water supply for the region. These include development of over 114,000 AF per year of additional local supply by 2030; reduction of imported water dependency by 25% via conservation and local supply development by 2030; diversification of supplies including expanded groundwater, new desalination of brackish groundwater, new recycled water, conjunctive use storage~~

~~and water transfers. These and other efforts described in the IRWMP will enable RCWD to continue to meet or exceed water demands within RCWD's service area.~~

RCWD's population is anticipated to increase to over 162,000 by 2035, requiring system improvements to ensure reliability of water supply. Local water management strategies implemented by RCWD to address water supply reliability for the region include: reduction of imported water dependency through ongoing conservation programs; budget-based tier rates; conjunctive use for optimized groundwater recharge and recovery strategies; and, an advance-treated recycled water program for expanded recycled water use. (RCWD, June 30, 2014)

In compliance with the Urban Water Management Planning Act, RCWD prepares an Urban Water Management Plan (UWMP). The UWMP includes an assessment of water sources and supply, reliability of supplies, water use efficiency measures, and water demand and supply comparisons. In addition, recent legislation under the Water Conservation Bill of 2009 requires urban water suppliers to report in their UWMPs a base daily per-capita water use ("baseline"), urban water use targets for the year 2020 and interim water use targets for the year 2015. This information will be included in RCWD's 2015 UWMP, which will be released by December 31, 2015. RCWD also has a Regional Integrated Resources Plan (IRP) to develop a long-range water supply plan to reliably meet the needs of the District through 2050. The IRP addresses issues of imported water supply availability, system capacity constraints, rising imported water costs and water quality.

As set forth in the information and analyses provided for MWD (see Section 4.19.4.E), including MWD's 2010 RUWMP, MWD has determined that it is capable of meeting demands for imported water throughout its service area over the next 20-year planning horizon and beyond during normal, single-dry and multiple dry-year periods. RCWD ~~and EVMWD obtain their~~ *obtains its supply of imported* water from MWD via EMWD and WMWD*, as noted above*. ~~As detailed above,~~ MWD strategically manages water in times of surplus to ensure adequate and reliable supplies during a shortage. ~~Even though MWD can reliably meet RCWD's demands, there is a capacity constraint issue associated with the turnouts from MWD pipelines. This will potentially cause future peak day water shortages after 2025 for RCWD.~~

Box Springs Mutual Water Company: According to WMWD (2010 UWMP), this water purveyor (BSMWC) has approximately 585 service connections in a 430-acre service area and is connected to WMWD's distribution system. BSMWC currently receives water from one BSMWC-owned well located in the Riverside South Groundwater Basin. In 2005, BSMWC's water purchases from WMWD totaled roughly 86 AF and 87 AF in 2010. The purchased water is used for blending purposes.

Eagle Valley Mutual Water Company: Eagle Valley Mutual Water Company was established in the late 1950s as a privately-owned mutual water company to serve non-potable irrigation water to an agricultural area of approximately 3,070 acres in Eagle Valley, west of Lake Mathews. It is anticipated that as long as its service area has agricultural lands, the water company will continue to be a viable operating agency. Eagle Valley has no groundwater pumping at this time. Eagle Valley purchased 652 AF of water from Western in 2009.

Jurupa Community Services District: The Jurupa Community Services District (JCSD) serves approximately 91,000 customers in a 42-square-mile service area in the northwest corner of Riverside County. JCSD does not currently receive imported water from Western, but JCSD is in the planning stages of developing supply and conveyance to augment existing water supplies with imported water. See Section 4.19.4.I (Local Water Providers Relying on Groundwater Only) for more information on Jurupa CSD water services.

(2) Other Agencies in WMWD's Service Area

There are several agencies in the WMWD service area that do not currently purchase water from WMWD. These agencies are briefly described below.

Elsinore Water District: EWD was formed in 1933 to provide potable water services to the Lake Elsinore area. EWD provides retail domestic potable water and recycled/reclaimed water distribution to a service area of approximately seven square miles with approximately 1,700 service connections. It does not provide wholesale water, sanitary sewer services or wastewater treatment. It maintains two separate water distribution systems both of which are located in older parts of Lake Elsinore and surrounding unincorporated areas and supplies water from EVWD and from local wells. (It does not import water directly from WMWD, but does get water from EVWD which does itself import from WMWD.)

LAFCO reports that the 2004 water demand in the EWD service area was 454 AF per year with an existing supply of 460 AFY. Future (2025) supply and demand data was not available. As indicated by its supply and demand data, EWD has sufficient water and infrastructure to serve its existing customers into the future. However, as part of the 2005 municipal service review, LAFCO concluded, "EWD is essentially built out." The ability of EWD to serve new development has not been verified.

Home Gardens County Water District: Home Gardens County Water District (HGCWD) was established in 1979 as a county water district. With its formation, it acquired the assets and facilities of the Home Gardens Mutual Water Company. HGCWD serves an area of more than 230 acres in the Riverside County area east of Temescal Street and south of Sampson Avenue. It has approximately 800 metered services for a population of approximately 3,000 people. Initially, HGCWD served its customers with local groundwater from wells in the Arlington Basin. However, because of the basin's poor water quality, the district has discontinued much of its well supply. Currently HGCWD receives approximately two-thirds of its water from the City of Riverside. It does not import water from WMWD.

Riverside Highlands Water Company: RHWC provides domestic and irrigation water services to the City of Grand Terrace, portions of the City of Colton and portions of unincorporated Riverside and San Bernardino Counties. It serves approximately 12,000 people in a service area of roughly 5,500 acres. All of RHWC's water supply originates from groundwater wells located in the Riverside North and South Basins and the Bunker Hill Basin. It does not import water from WMWD.

Rubidoux Community Services District: Rubidoux Community Services District serves roughly 27,000 customers in a 120-acre service area. All of Rubidoux CSD's potable water supply is obtained from extraction wells located within its own boundaries, except for emergency water supplies delivered through interconnections with JCSD and West Valley Water District. Rubidoux CSD's wells extract water from the portion of the Riverside Basin lying within Riverside County. In 2009 Rubidoux pumped and delivered approximately 6,600 AF to its customers. It does not import water from WMWD. See Section 4.19.4.I for more information on Rubidoux CSD water services.

Santa Ana Water Company: The SAWC was established in 1925 and is a privately held, independently operated mutual water company. It serves an area surrounded by Jurupa CSD in unincorporated Riverside County (and, now the cities of Jurupa Valley and Eastvale). The SAWC utilizes water from the Chino Basin Desalter Authority, water leases with Jurupa CSD and also local groundwater. It does not import water from WMWD.

3. San Bernardino Valley Municipal Water District

SBVMWD covers about 325 square miles in southwestern San Bernardino County and serves a population of 576,000. SBVMWD imports SWP water and manages groundwater storage within its boundaries, which include groundwater basins located partially within Riverside County. Specifically, LAFCO (2002) reports that SBVMWD is responsible for monitoring groundwater supplies in the San Bernardino and Colton-Rialto basins and maintaining flows at Riverside Narrows on the Santa Ana River. The district's current water supplies are comprised of 68% groundwater, 17% imported, 14% surface water, less than 1% recycled.

As one of MWD's 26 member-agencies, SBVMWD receives imported water supplies from Northern California via the SWP and provides wholesale water to 11 retail sub-agencies of its own. It does not directly serve any retail water customers of its own. Two of SBVMWD's retail agencies, the West Valley Water District and Yucaipa Water District, are located within Riverside County (see discussion below). SBVMWD also receives exported (recycled) water from the City of Riverside. Unless otherwise noted, the information in this subsection comes from the 2010 San Bernardino Valley Regional Urban Water Management Plan (RUWMP, for this subsection), which was prepared by Kennedy/Jenks Consultants, June 2011, and addresses, in addition to SBVMWD, the San Bernardino Municipal, East Valley, West Valley and Yucaipa Valley water districts, as well as the water agencies for the cities of Loma Linda, Redlands and Colton.

a. Notes on SBVMWD

SBVMWD was formed in 1954, under the Municipal Water District Act of 1911 (CWC Section 71000 et seq.) as a regional agency to plan a long-range water supply for the San Bernardino Valley. Its enabling act includes a broad range of powers to provide water, wastewater and stormwater disposal, recreation, and fire protection services. SBVMWD does not deliver water directly to retail water customers. SBVMWD monitors and manages the groundwater supplies (and recharge) in the San Bernardino and Colton-Rialto basins and maintains flows at Riverside Narrows on the Santa Ana River.

SBVMWD's services are provided to a population of about 657,500. The district spans the eastern two-thirds of the San Bernardino Valley, plus Crafton Hills and a portion of Yucaipa Valley. It also includes the cities and communities of San Bernardino, Colton, Loma Linda, Redlands, Rialto, Fontana, Bloomington, Highland, East Highland, Grand Terrace, Mentone and Yucaipa; most of which are in San Bernardino County. A map illustrating district's service area, along with the service areas of the retail water purveyors, is provided in Figure 4.19.23 (Map of SBVMWD's Service Area). In the 2010 RUWMP, the district estimated a future population projection for 2015 to 2035, based on the amount of San Bernardino County served (35%) and Riverside County served (0.01%). According to the RUWMP, by 2015, SBVMWD expects to serve nearly 717,800 residents, 832,600 residents by 2025 and nearly 940,000 by 2035.

The climate within SBVMWD's service area is characterized by warm, dry summers and mild winters with moderate amounts of rainfall. Mean annual temperatures average 64.1°F, with summer high temperatures (June through September) in the low 80s and winter lows in the upper 30s. The average annual maximum monthly temperature is 79.9° F. The average annual precipitation is 16.1 inches, most of which occurs between December and March.

b. SBVMWD Water Availability

To better manage water resources to a burgeoning population within a dry climate, SBVMWD is actively involved in several regional projects that will improve water reliability and water quality. The district is exploring a broad array of water management measures, including water waste prevention and water loss control that will be implemented in 2012. The district expects to expand its recycled water supply from 1% to 7% to meet future water demands.

Table 4.19-AH: San Bernardino Valley Municipal Water District Background Information

Sub-Agencies Served[1]			Cities Served[2]
East Valley Water District[5]	Fontana Union Water Co.[5]		City of San Bernardino[5]
West Valley Water District	Fontana Water Company[5]		City of Loma Linda[5]

Service Area Statistics[3]			
Size	208,000 acres	***CA Hydrologic Region***	South Coast
Population	657,500 people	***Regional WQCB***	8 – Santa Ana

Services Provided[3]					
Distribution	X	Wholesale Water	***Operations[4]***	X	Potable Water Treatment
	_	Retail Water		_	Desalination
	_	Recycled or Non-Pot. Water		X	Groundwater Recharge
	_	Wastewater (Collection)		_	Wastewater Treatment

Footnotes:
1. Unless noted otherwise, the district provides wholesale water to these sub-agencies.
2. City/community may be served by this district either wholly or partially. Areas in which only a small fragment are served by the water district or are outside of the district's formal service area may be omitted for clarity.
3. Services and service area statistics from Riverside LAFCO, 2005 Water and Wastewater Municipal Service Review.
4. Only facilities operated directly by the listed water agency included.
5. Serves only San Bernardino County territory.
6. Due to a boundary adjustment, a small sliver of Riverside County falls within this district.

Source: Kennedy/Jenks Consultants. 2010 SBV RUWMP, 2011; Riverside LAFCO. Water and Wastewater Municipal Service Review Report, 2005.

A second strategy for addressing water supply during an emergency is to ensure system redundancy. To that end, SBVMWD has identified alternative conveyance facilities which could be used in the event of a failure of one of district's pipelines. For example, the district has an agreement with MWD which could allow the use of the Inland Feeder Pipeline to bypass a large portion of the Foothill Pipeline, the district's primary delivery line. In addition, the SBVMWD proposes to develop the following facilities that would create additional system redundancy:

Table 4.19-AI: SBVMWD Water and Wastewater Service Data

WATER SERVICE DATA					
Water Supply (AF)		**Water Connections**		**Water Service Capacity**	
Wholesale	All	Domestic	NP	Total Capacity (AF)	299,100

Key: NS = not specified

Footnotes:
1. All data from SBV-RUWMP, unless noted otherwise. All data rounded to nearest hundred.
2. All data is for the regional water supply, that is, the water agencies covered by the RUWMP (see Table 4.19-AH).
3. Water years used for average, single-dry years not specified. Various years used for the multi-year dry data.
4. Includes SBBA surface water, Seven Oaks supply and Glen Oak.
5. Groundwater includes SBBA groundwater, SBBA return flows extraction above the safe yield and groundwater from the Rialto-Colton, Riverside North and Chino basins, as well as Yucaipa, Beaumont and San Timoteo.
6. Assumes SWP water is stored in wet years so it can supplement lower deliveries of SWP imports in dry years.
7. From Tables 4-1, 4-2 and 4-3 of the SBV-RUWMP.

Source: Kennedy/Jenks Consultants. 2010 SBV RUWMP, Tables 2-8, 2-9, 2-10, 4-1, 4-2, 4-3 and 6-1, 2011.

- **Central Feeder Pipeline:** The Central Feeder Pipeline System parallels the Foothill Pipeline and could allow groundwater to be delivered to customers along the East Branch Extension of the California Aqueduct if the Foothill Pipeline was not available to deliver SWP water.

- **Ninth Street Feeder:** This project would provide an interconnection between the East Valley Water District and SBVMWD's Baseline Feeder Extension South Pipeline.

SBVMWD is also developing a storage program to help meet direct delivery demands during a shortage of SWP water. The current storage program includes the DWR's Carryover Storage Program, the Yuba Accord and the DWR Dry Year Water Transfer Program. SBVMWD is also evaluating 'upstream' groundwater banks located along the California Aqueduct as well as Big Bear Lake. Finally, SBVMWD is planning to implement seismic improvements for high priority facilities, including the Foothill pipeline, Santa Ana River connector, Morton Canyon connector and Greenspot pipeline.

In recent years, water conservation has become an increasingly important factor in water supply planning in California. DMMs are programs and activities through which a water supplier can communicate with their customers and encourage, regulate or incentivize water conservation. The Urban Water Management Planning Act identifies 14 DMMs that are to be evaluated in each UWMP. DMMs include hiring a conservation coordinator to manage water conservation efforts, enacting ordinances or terms of service that prohibit water waste and require water-efficient design in new development, as well as enacting ordinances developing water shortage response measures.

Although SBVMWD is not a retail agency, it does support water waste prohibition and water conservation. Consistent with its DMMs, the district actively supports its retailers through a variety of programs including: school education programs and emphasizing the use of water friendly planting through the district's Inland Empire Garden friendly Program. In recent years, SBVMWD performed a water loss audit, engaged in a variety of public information programs concerning water waste prevention, provided $500,000 for a demonstration garden at California State University of San Bernardino, engaged in conservation-related education programs through local school districts and contributed $430,000 in financial incentives to upgrade inefficient irrigation controllers to weather-based controllers.

Because it is a wholesale agency, SBVMWD is not directly implementing water survey programs for single-family residential and multifamily residential customers, residential plumbing retrofits, metering with commodity rates, large landscape conservation programs, high efficiency washing machine rebate programs or other such programs. Instead, the district supports their retail agencies with their conservation programs. Further, the RUWMP emphasizes a greater reliance on recycled water and seeks to expand that resource from 1% to 7% of its water supply. SBVMWD's UWMP concludes that the district has the water supply to meet or exceed demands in a normal year, single dry year and multiple dry year period through the year 2035.

c. Sewer and Wastewater Treatment Services in the Region

The SBVMWD does not provide any wastewater treatment services. Within SBVMWD's service area, according to the RUWMP, sewage collection and wastewater treatment services are provided by several retail agencies. In particular, sewer collection systems are provided by the County of San Bernardino, the East Valley Water District and the cities of San Bernardino and Loma Linda.

One of the region's two major wastewater treatment plants is the San Bernardino Regional Wastewater Treatment Plant (SBRWTP) in the City of San Bernardino, which has a capacity of 33 mgd (or just under 37,000 AFY). Although as of 2010, flows only averaged around 29,000 AFY, the SBV-RUWMP calls for production to reach over 35,200 AFY by 2035. A number of local providers convey their sewage to this plant for treatment to secondary standards. From the SBRWTP, the effluent is then sent to the Rapid Infiltration/Extraction (RIX) Plant in the City of Colton and treated to Title 22 tertiary standards using natural biofiltration via percolation basins followed by ultraviolet disinfection.

In this way, the RIX can treat up to 41 mgd of secondary effluent. It produced 33,000 AF in 2010 and is projected to reach just over 40,000 AFY by 2035. Ultimate capacity is 45,000 AFY per the RUWMP (page 10-31). RIX-treated wastewater consistently meets or exceeds required discharge standards and is often superior in quality to effluent produced by conventional tertiary treatment facilities. Ultimately, the RIX water is discharged to the Santa Ana River to meet a 16,000-AFY obligation for downstream recharge. Amounts beyond this may be made available for future resale.

The East Valley Water District provides sewage collection services to its members (roughly 7.3 mgd) and conveys the sewage to the SBRWTP. The City of Loma Linda also sends its sewage (up to 7 mgd) to the SBRWTP. Wastewater collected by the West Valley Water District (WVWD) is treated mainly by the City of Rialto, with facilities run by the City of Colton and the Inland Empire Utilities Agency handling the rest. Rialto's plant processes 8 mgd to Title 22 standards for "restricted irrigation." Unused reclaimed water is discharged into the Santa Ana River. The City of Redlands also operated a wastewater treatment facility that produces up to 6 mgd of high-quality tertiary effluent (its maximum capacity is 7.2 mgd per RUWMP, page 9-28); roughly 6,000 AFY total. From this source, the city supplies recycled water (roughly 2,200 AFY) to Southern California Edison for its use as cooling water for its Mountain View power plant. The rest is disposed of via percolation ponds for recharge.

The Yucaipa Valley Water District (YVWD) collects and conveys wastewater through roughly 160 miles of sewer lines to its Wochholz Regional Water Recycling Facility. The RUWMP (page 12-39) reports that this facility was recently expanded to a 6.7-mgd wastewater treatment capacity, with a 10-mgd advanced tertiary treatment capacity ultimately planned. Water from the Wochholz facility (approximately 920-1,075 AFY) is currently discharged into San Timoteo Creek and used by three irrigation customers. Ultimately, YVWD's recycled water production is projected to reach 8,000 AFY.

The City of Colton provides wastewater collection and treatment services to customers within its service area through the system it owns, operates and maintains. Colton also jointly owns, with the San Bernardino Municipal Water District (note, this is not SBVMWD), the RIX facility. Wastewater conveyed to Colton's WWTP undergoes secondary treatment processes in compliance with Santa Ana RWQCB regulations and is then conveyed to RIX for tertiary treatment and reuse or discharge.

SAN BERNARDINO VALLEY MUNICIPAL WATER DISTRICT SERVICE AREA

This page intentionally left blank.

d. SBVMWD Subagencies

As listed in Table 4.19-AH, above, SBVMWD supplies wholesale water to a number of subagencies, most of which are located in San Bernardino County. Two, however, serve portions of Riverside County: West Valley Water District and Yucaipa Water District. The City of Riverside (with the Gage Canal Water Company) also exports water from the SBVMWD service area. These local sub-agency providers are summarized briefly below.

West Valley Water District: WVWD, formerly known as the West San Bernardino County Water District, provides retail water service to an area of approximately 19,000 acres; 310 acres of which lie within Riverside County according to LAFCO (2005). Its population was roughly 66,600 people in 2010. WVWD estimated that there were 150 metered connections within Riverside County in 2002 and the total will reach a maximum of 250 connections at build out. WVWD relies on a combination of imported, ground, surface (Lytle Creek) and recycled water to meet demand. Imported water is purchased from SBVMWD (7,000 AFY) and groundwater is extracted from five basins. WVWD shares the Chino, Bunker Hill and North Riverside basins with the cities of Norco and Riverside, as well as Jurupa CSD. According to the RUWMP (page 11-27), WVWD has the capacity to produce up to 36 mgd, but typically meets its demand running at only two-thirds that capacity. As of 2010, it had 25 reservoirs with a total storage capacity of approximately 72.6 million gallons. The district also operates a 9.6-mgd water filtration facility. According to LAFCO, water demand for 2025 will be below the ultimate expected demand within WVWD's service area.

Yucaipa Valley Water District: According to LAFCO (2005), the YVWD provides water, wastewater and recycled water service to customers in the cities of Calimesa and Yucaipa, as well as portions of both unincorporated San Bernardino and (a small portion of) Riverside Counties. Located at the upper portion of the Santa Ana Watershed, it is within the service area of two SWCs, the San Gorgonio Pass Water Agency, in addition to SBVMWD. According to the RUWMP (page 12-1), YVWD's service area spans 40 square miles (nearly 25,800 acres). Its service area also includes the Western Heights Water Company and the South Mesa Water Company, which span 2,900 and 2,560 acres, respectively. In the past, YVWD has sold water to both these companies due to lack of groundwater in their service areas (RUWMP, page 12-6).

YVWD produces groundwater from the San Timoteo Subbasin and the "Beaumont Groundwater Basin," which according to the RUWMP (page 2-12) is composed of three other groundwater basins (primarily the San Timoteo, Upper Santa Ana Valley and the San Gorgonio Pass subbasins). Both basins are located in Riverside County and outside the SBVMWD service area. Approximately 530 AFY was pumped from the Beaumont basin by YVWD in 2008-2009. (Though in total, YVWD pumps groundwater from a total of 11 different area basins per RUWMP Figure 12-3). YVWD operates a surface water treatment plant (with water rights from Wildwood Canyon and Oak Glen) capable of producing up to 1 MGD. It also has 22 above-ground storage tanks (reservoirs) to provide operational storage, as well as water for emergencies and fire protection needs.

YVWD operates the Yucaipa Valley Regional Water Filtration Facility, which processes imported (SWP) water to tertiary standards. The plant's treatment capacity was recently expanded to 8 mgd. The plant uses microfiltration filters and ultraviolet light for disinfection. Plans are underway to add reverse osmosis as well, along with a 15-mile brine line for waste disposal, which began construction in 2010. The plant provides 2,000 AFY of potable water of exceedingly high quality after processing.

According to the RUWMP (page 12-26), YVWD purchased approximately 6,500 AF of wholesale water from SBVMWD in 2010 and plans additional purchases into the future: 7,900 (2015), 8,300 (2020), 8,700 (2025), 9,000 (2030) and 9,400 (2035). YVWD also purchased 700 AF of wholesale water from the San Gorgonio Pass Water Agency (SGPWA) in 2010 and plans to purchase additional water from this agency as well: 1,800 (2015), 2,300 (2020), 2,800 (2025), 3,600 (2030) and 4,500 (2035). By 2010, YVWD imported 28% of its supply. This increased

use of imported water has somewhat eased demand on local groundwater, as has the district's use of recycled water for up to 10% of its demand.

4. Jurupa Community Services District

The Jurupa Community Services District (JCSD) was formed in 1956 for the purpose of providing a sewer system to the community of Jurupa, which is now in the newly incorporated City of Jurupa Valley (roughly two-thirds of which is served by JCSD). JCSD also serves virtually all of the newly incorporated City of Eastvale. However, since these new city incorporations post-dated the initiation of this EIR, this information is included here to ensure a comprehensive water analysis.

The JCSD encompasses an area of 48 square miles in Riverside County and serves approximately 101,700 customers. Its service area includes portions of unincorporated Riverside County in the communities of Pedley, Glen Avon, Sunnyslope and Mira Loma. It also serves several areas outside the district boundary, according to LAFCO (2005). See Figure 4.19.24 (Jurupa and Rubidoux Community Service Districts Service Areas). In addition to water and sewer services, it also provides a variety of critical services such as water, sewer, street lights, frontage landscape maintenance and graffiti abatement. JCSD is also responsible for parks maintenance and recreation programming within its parks territory (i.e., not every service is provided in every area).

Although a member agency of WMWD, JCSD relies on groundwater to serve its customers and does not import water from Western. It does, however, implement conservation programs through WMWD. Unless noted otherwise, the information in this subsection comes from JCSD's 2010 Urban Water Management Plan ('UWMP,' for this subsection).

a. Notes on JCSD

With 16 wells, eight booster stations, 15 reservoirs and a total capacity of 53.7 million gallons, JCSD relies predominantly on groundwater and desalinated brackish groundwater from the Chino Groundwater Basin. JCSD currently has 16 wells, eight booster stations and 15 reservoirs of 53.7 million-gallon capacity. There are two small irrigation water systems located in JCSD, one in Sunnyslope and the other in Eastvale.

The majority of JCSD's service area overlies the Chino Basin, with the remainder over the Riverside Groundwater Basin. The primary source of local groundwater is the Chino Groundwater Basin, consisting of approximately 154,000 acres, which is a part of the Upper Santa Ana Valley groundwater basin. JCSD has rights to groundwater pumping in the Chino Basin through the adjudication and to contract amounts of the Chino desalters. The Chino Basin was adjudicated in 1978 pursuant to a Judgment entered in the Superior Court of the State of California for the County of San Bernardino. Pumping within the basin is managed and reported by the Watermaster, with management activities implemented through an Optimum Basin Management Program (OBMP) that was developed for the Chino Basin in 2000. Safe yield of the Chino Basin is 140,000 AFY; this total is allocated among the overlying agricultural pool (82,800 AFY), the overlying non-agricultural pool (7,400 AFY) and the appropriative pool (49,800 AFY). Water produced in excess of a user's scheduled allotment is charged at a higher rate. Thus, the quantity and availability of groundwater from the Chino Basin is more a matter of the cost than a limitation on JCSD's access to groundwater supply or distribution capabilities.

The JCSD participates in the Chino Desalter Authority (CDA), a joint powers authority, with other neighboring water purveyors using the Chino Basin. The CDA owns and operates two water treatment plants (desalters) for the removal of TDS and nitrates in the Chino Basin, along with 22 wells, pipelines, two booster pump stations and two reservoirs for delivery of this highly treated water. Both desalters utilize reverse osmosis and ion

exchange treatment processes to remove the nitrates from the groundwater. The treatment capacity for each plant is 12 mgd. JCSD has a contractual obligation to purchase 7.8 mgd (8,200 AFY). The CDA expanded capacity beyond the Chino I desalter by adding the Chino II desalter which processes 10.5 MGD; for a total of 22.5 MGD. In addition, the Chino II desalter is being expanded to 20.5 MGD, with JCSD contracted for 3 MGD (3,300 AFY) of that output.

JCSD also operates three sewer systems that each discharge wastewater to different treatment plants. JCSD's Regional Lift Station pumps wastewater to the City of Riverside's Regional Water Quality Control Plant. Second, the Community Finance District (CFD) No. 1 wastewater system is mostly from industrial sources and is discharged to the Inland Empire Brine Line (IEBL), formerly known as the Santa Ana River Interceptor (SARI) System, for treatment in Orange County, which has higher salt limits because it discharges to the Pacific Ocean. Lastly, the Eastvale area discharges to the River Road Lift Station, which pumps the wastewater to another regional treatment plant, operated by the Western Riverside County Regional Wastewater Authority (WRCRWA), of which JCSD is a member. The WRCRWA plant, which is located within JCSD's service area, has a 3.25-mgd capacity.

b. Water Supplies

JCSD obtains its groundwater supplies from the Chino and Riverside basins. In total the groundwater supplies in the JCSD service area include three sources of water: potable and non-potable water is pumped from the Chino Basin; groundwater is also extracted from the Chino Basin and treated by the Chino I and II desalters; and, non-potable-use groundwater is also pumped from the Riverside Basin.

Local groundwater supplies from the Riverside Basin (a portion of the Riverside-Arlington Subbasin, No. 8.2-03) represent a small supplemental source of water for JCSD. The district's non-potable water wells are in the Riverside South portion of the Riverside Basin; it is the portion of the basin within Riverside County (the Riverside North portion is within San Bernardino County). As of November 2008, groundwater management planning spearheaded by Riverside Public Utilities (RPU) for the Riverside Groundwater Basin has resulted in issuance of a draft Groundwater Management Plan.

Chino Groundwater Basin, identified in the DWR Bulletin 118, 2003 Update, as the Chino Subbasin (No. 8-2.01) which is a part of the Upper Santa Ana Valley Groundwater Basin. The Chino Basin is the largest groundwater basin in the Upper Santa Ana River Watershed, consisting of approximately 240 square miles (154,000 acres). The majority of JCSD's 48-square mile service area overlies the Chino Basin; the remainder of the service area overlies the Riverside Basin. JCSD has rights to groundwater pumping in the Chino Basin through adjudication and contracts with the Chino desalters, as per above.

The Chino Basin itself is located within portions of the counties of San Bernardino, Riverside and Los Angeles. It is bounded on the north, south, east and northwest by earthquake faults (Cucamonga, Chino, Rialto-Colton and San Jose faults, respectively). It is also bounded by the impermeable rocks of the Jurupa Mountains to the southeast, Puente Hills to the south and San Gabriel Mountains to the north. San Antonio and Cucamonga creeks drain the surface of the basin southward to join Santa Ana River, which flows on towards its Pacific Ocean outlet in Orange County. Annual mean precipitation ranges from 13 to 29 inches across the surface of the basin and averages about 17 inches, per the Bulletin 118 Update (DWR, 2003).

The saturated sediments in the Chino Basin include a shallow aquifer system and at least one deep aquifer system. The shallow aquifer system is generally characterized by unconfined to semi-confined groundwater conditions, high permeability within its sand and gravel units and high concentrations of dissolved solids and nitrate (especially in the basin's southern portions). The deep aquifer system is generally characterized by confined groundwater conditions, lower permeability within its sand and gravel, and lower concentrations of dissolved solids and nitrate (JCSD UWMP, page 30).

Groundwater in the Chino Basin generally flows in a south-southwest direction from the primary areas of recharge in the northern parts of the basin toward the Prado Flood Control Basin in the south. The Chino Basin's Watermaster has three active, comprehensive groundwater-level monitoring programs to collect basin-wise groundwater level data. The groundwater level monitoring program is comprised of about 700 wells, with water level data collected quarterly with the assistance of several partner agencies. The wells in the monitoring program within the southern portion of the basin were mainly selected to assist in Watermaster's monitoring programs for desalter impacts to private well owners, hydraulic control and land subsidence (JCSD UWMP, page 36).

Source: Riverside LAFCO. Water and Wastewater Municipal Service Review Report: Western Riverside County and Coachella Valley, 2005.

The projected groundwater pumping by JCSD in the Chino Basin and Riverside Basin is summarized in Table 4.19-AM (JCSD Water Supply and Demand Summary). JCSD produces water from groundwater sources from the Chino Basin, which was adjudicated by the Judgment in 1978 (Appendix C). The Judgment represents a plenary adjudication of all water rights in the Chino Basin and is administered under the authority of the Watermaster with continuing jurisdiction by the Court. The Judgment declares that the safe yield of the Chino Basin is 140,000 AFY, which is allocated among the three pools as follows: the overlying agricultural pool (82,800 AFY); the overlying non-agricultural pool (7,366 AFY); and, the appropriative pool (49,834 AFY). The Judgment recognizes that there is a substantial amount of available groundwater storage capacity in the Chino Basin that can be utilized for storage and conjunctive use of supplemental water and basin waters. Utilization of this storage capacity is subject to Watermaster control and regulation.

Of JCSD's historical total groundwater pumping from 2005 to 2009, including pumping from the JCSD's existing wells, CDA purchased desalinated water and pumping from the Riverside Basin, on average, about 81-97% of the

water used in the service area was from groundwater extraction. The majority of pumping was in the Chino Basin, pursuant to the Judgment and through the CDA (UMWP, page 40).

JCSD's existing potable water supply comes from 16 wells, all located within JCSD's service area and drilled within the Chino Basin. JCSD's historical pumping for potable use from its existing wells ranged from 15,975 AF in 2009 to 19,747 AF in 2008. Groundwater production in 2009 was less than during the previous four years which is indicative of the recent rate increases, drought conditions and poor economic conditions.

JCSD's existing potable supply well field has a current maximum production capacity of nearly 26,000 gpm potable water (41,900 AFY) as of 2010. However, JCSD does not operate its wells at maximum capacity (i.e., 24 hours per day, 365 days per year) and only uses its maximum capacity during maximum day and peak hour conditions and for redundancy. The existing well field annual production capacity is just under 28,000 AFY for 2010, which is roughly two-thirds the maximum capacity. Historical potable well pumping between 2005 and 2009 has also been below JCSD's well field capacity. The UWMP indicates JCSD's future pumping projections are also below the current well field production capacity of 28,000 AFY and potential future production capacity of 54,000 AFY.

JCSD also receives groundwater extracted from the Chino Basin and treated at the CDA's Chino I and II desalters. Between 2005 and 2009, JCSD purchased roughly 3,500-8,900 AF through the CDA. JCSD's current delivery from the CDA is 8,200 AFY and an additional delivery capacity of 3,300 AFY to JCSD is anticipated by 2015 from the proposed Chino II desalter expansion.

Groundwater quality in the lower Chino Basin is poor, as nitrate and TDS exceeding drinking water standards. Nitrate and TDS intrusion are primarily from historic dairy and agricultural users. Other water quality concerns include the presence of perchlorate, VOCs and other chemicals associated with airport cleanup sites (Ontario International and Chino airports). The Chino Watermaster continues its active role in cleanup sites across the basin. Water quality issues in the Chino Basin have been addressed by the completion of desalter facilities and the installation of well head ion exchange treatment facilities. Water quality produced from these facilities is within standards set for acceptable drinking water by the federal government and the California Department of Public Health (DPH). Water quality in the Riverside South Basin is not a major issue, as it is a minor contributor to JCSD's supplies.

In addition, JCSD currently uses non-potable irrigation wells to extract water from the Chino Basin. Between 2005-2010, JCSD used up to six non-potable wells to produce 200-260 AFY of groundwater. From the Riverside Basin, non-potable groundwater pumping comprised only a small portion of total groundwater pumping, ranging from 267 to 605 AFY during 2005 and 2009. Transfer opportunities currently available in the JCSD service area include the current and future projected transfers from the Rubidoux Community Services District (RCSD), as well as a long-term lease of Chino Basin pumping right from the Santa Ana River Water Company (SARWC). Since 2000, JCSD has been purchasing water from RCSD, which extracts its water from the Riverside South Basin. In 2009, JCSD purchased 480 AF from RCSD. JCSD has opened negotiations with RCSD to purchase additional water from them in the future. Total water transfer from Rubidoux CSD is projected to be 1,500 AFY. JCSD also has a long-term lease from the SARWC of up to 1,200 AFY. The groundwater is pumped using JCSD facilities but is tracked in accordance with the Judgment and the lease agreement.

At present, about 700 AFY of non-potable water is used for irrigation in the district. However, the future water demand in the JCSD service area will increase as development continues and thus could be an important and reliable source of additional water. Up to 4,300 AFY of existing and future irrigation demand in the JCSD service area, such as public facilities including parks, medians, schools and golf courses, could be supplied by non-potable water. Detailed evaluations of existing and future non-potable water demands throughout the service area were

performed that evaluated potential alternatives with non-potable water sources – a "Draft 2008 Non-Potable Water Master Plan" and "2010 Non-Potable Water Evaluation in the Eastern Portion of JCSD Service Area." Currently, JCSD and other entities meet approximately 42% (approximately 1,800 AFY) of their total irrigation demands with non-potable well water. The total estimated future additional demand that could be met by non-potable water is 2,500 AFY. Thus, total ultimate irrigation demand, existing and future, is estimated to be 4,200 AFY. It is projected that up to 500 AFY of recycled water will be available from the WRCWRA plant. JCSD has been working with WMWD to discuss the feasibility of using this recycled water.

c. JCSD Water Demand

Table 4.19-AM shows current and projected water demands for both potable and non-potable water. The water serves a range of customer types, including single-family and multi-family homes, commercial, industrial, institutional, government, landscape and agriculture. Single-family residential represents 70% of the water demand, with landscape irrigation at 10% and agricultural at 1%.

The impact of low precipitation in a given year on a particular supply may differ based on how low the precipitation is, or whether the year follows a high-precipitation year or another low-precipitation year. Within JCSD, the water supply is predominantly from local groundwater and the groundwater basin is recharged from surface supplies. The Chino Basin Watermaster oversees recharge and overdraft prevention within the Chino Basin. Groundwater recharge occurs from the following sources: stormwater, SWP water provided by MWD and recycled water.

To further project its groundwater supply, JCSD is currently pursuing an option to acquire up to 10,000 AFY from WMWD through the proposed Riverside-Corona Feeder Project. This proposed connection to WMWD is to be constructed by 2020 and would provide an additional source of water for JCSD. The feeder project would allow WMWD to purchase SWP water from MWD during wet years when it is available and store it in the San Bernardino Groundwater Basin. Then, it can extract the water from this basin when it is needed in years of drought.

JCSD has a diverse portfolio which currently includes a connection to another agency (Rubidoux CSD), access to the CDA and local groundwater including a lease of up to 1,200 AFY of water rights from the Santa Ana River Water Company (SARWC). Membership also allows access to other sources of supply from the six other CDA members (WMWD, SARWC and the cities of Ontario, Norco, Chino and Chino Hills). To ensure reliability, JCSD intends to increase their water portfolio by pursuing water from WMWD via the Riverside Corona Feeder, the Riverside Basin and recycled water. Water pumped in excess of safe yield is available for pumping but is charged a higher rate in order to cover the cost of replenishment. Stormwater, imported water from the SWP and recycled water contribute to the recharge of the Basin.

As shown above, JCSD has adequate supplies to meet demands during normal, single-dry and multiple-dry years throughout the 20-year planning period. There is no difference in the supply and the demand since the local groundwater supplies are pumped according to the demand. In addition, there is more than sufficient production capacity to meet future demands.

The JCSD manages a water conservation program that includes actively pursuing incidents of waste and regulating sources for excessive leakage and facilities failure. It also has established conservation levels that are enacted in response to a water supply shortage pursuant to JSCD's Water Shortage Contingency Plan and Ordinance No. 317. They include increasing restrictions on water use in response to worsening drought conditions and decreasing available supplies.

The largest customer class in the JSCD service area is residential, accounting for approximately 94% of connections and 70% of total demand. JSCD has nearly 25,400 single- and multi-family residential accounts. Accordingly, JCSD focuses the majority of its conservation efforts on residential use, including offering a number of rebates, educational materials and audit programs. In addition, all water deliveries are metered and all new water service accounts require meters. Likewise, large landscapes, including landscaped medians, greenbelts, parks and golf courses, have dedicated irrigation meters. In addition, the limited agriculture in the region is monitored with individual meters.

Under its Ordinance No. 317, JCSD has developed a four level rationing plan to be invoked during declared water shortages. The rationing plan includes voluntary and mandatory rationing, depending on the causes, severity and anticipated duration of the water supply shortage. Mandatory prohibitions enacted during water shortages, e.g., drought, include educational programs and changes in water use.

d. JCSD Water Availability

As mentioned above, water rights within the Chino Basin were adjudicated in 1978. Pumping within the Chino Basin is managed and reported by the Watermaster. The principal function of adjudication is to control the use of a water source to ensure the source is utilized in an optimum manner.

The Chino Basin stores approximately 5 million AF of groundwater with the capability of storing an additional 1 million AF. For purposes of adjudication, the central feature is the determination of the safe yield of the basin. The Judgment established the safe yield of the Chino Basin as 140,000 AFY. Also as mentioned above, pursuant to the Judgment, the average safe yield of the Chino Basin is allocated among three "pools" of users. In the Chino Basin, groundwater is reallocated to the appropriative pool for urban use from the overlying agricultural pool when not pumped by the agricultural users.

The Watermaster may determine that the operating safe yield can be higher from year-to-year depending on factors including favorable precipitation and management efforts that maximize the beneficial use of the Chino Basin. Based on the historical records of pumping in the Chino Basin, as reported by the Watermaster, total pumping (basinwide) ranged approximately from 160,000 AF to 180,000 AF from 2000 to 2005 and started to decline in 2007. Pumping for the 2009-2010 production year was 114,496 AF.

The Judgment does not place specific limits upon the groundwater production by any party to the Judgment, including JCSD. Each of the parties to the Judgment, divided into three pools, are prohibited from pumping the basin in excess of their rights except under certain proscribed situations. In particular, additional groundwater production in excess of the safe yield is allowed by the adjudication provided that the pumped water is replaced with replenishment water. Historically, the Watermaster has purchased imported water from MWD to provide replenishment water when pumping exceeds the safe yield of the Chino Basin. Water from MWD is available via the Foothill Feeder. Since 2000, roughly 12,800 AFY of supplemental (SWP) water recharge has been provided to the basin (JCSD UWMP, page 45).

The Judgment expresses a clear expectation that its subject parties, including JCSD, would produce water in excess of their adjudicated production rights; provided, however, they must pay a replenishment assessment when production exceeds that amount. JCSD's ability to produce water from the Chino Basin is thus largely a matter of cost. Water produced in excess of a party's production rights costs more than water produced within a party's production rights. Thus, the quantity and reliability of groundwater supplies is a matter of the cost of the water produced from the Chino Basin rather than limitations on JCSD's access to groundwater supply.

The Riverside South Basin is not adjudicated and not identified as overdrafted nor is it projected by the DWR to become overdrafted. According to the UWMP (page 43), current and future projected pumping by JCSD in the Riverside Basin and projected pumping by other major pumpers (i.e., City of Riverside) in this basin are expected to be within sustainable yields since efforts to manage groundwater in the basin have been initiated; thus, availability of this local groundwater source for JCSD is not considered an issue.

In terms of water supply reliability, JCSD has various water supplies available to meet demands during normal, single-dry and multiple-dry years. After analyzing the various supply and demand issues associated with these varying conditions, the JCSD UWMP (page 82) finds that any supply deficits "will be satisfied with local groundwater." And that, "Overall, the Chino Basin is considered a reliable supply as the recharge is managed through the Chino Basin Watermaster with local and [MWD] replenishment water." Further, in its 2010 RUWMP, MWD indicated that it will be able to meet all demands during the next 20 year planning period. Even during multiple dry year periods with an assumed 10% increase in demand, the demand will be met. In addition, a regional message from MWD regarding water conservation during dry years, which can be reinforced by JCSD, will likely minimize increases in dry year demand.

5. Rubidoux Community Services District

Formed in 1952, the Rubidoux Community Services District (RCSD) was California's first community services district. Today, RCSD continues to provide retail domestic potable water, agricultural water treatment and distribution, wastewater collection and fire protection services to a community that has grown from 4,000 to over 26,000. The RCSD is now almost entirely within the eastern side of the newly incorporated (July 2011) City of Jurupa Valley. However, since the incorporation post-dated the initiation of this EIR, information on this district is included here to ensure a comprehensive water analysis for GPA No. 960. According to the district's UWMP, it also serves roughly 120 acres located in San Bernardino County.

The information presented in this subsection comes from the 2005 Riverside LAFCO report entitled, "Water and Wastewater Municipal Services Review," and RCSD's 2010 Urban Water Management Plan ('UWMP' for the purposes of this subsection), dated November 2011.

a. Notes on RCSD

As shown in Figure 4.19.24, RCSD's service area encompasses an 8.5-square mile service area with a service population of approximately 26,000 located wholly within the City of Jurupa Valley. RCSD's water supply and distribution system can provide over 8.0 million gallons a day (mgd) of potable water. The construction of a manganese removal plant and a nitrate treatment plant has afforded the district the opportunity to serve the community with water from existing groundwater supplies. The District also delivers 2.0 mgd to the Regional Wastewater Treatment Plant located in and operated by the City of Riverside. RCSD also sells water to the City of Norco and the Santa Ana Water Company.

b. RCSD Water Supply

As of December 2005, RCSD has over 6,800 metered connections, including 6,400 residential and 400 commercial/industrial. RCSD's water supply is obtained 100% from groundwater (the Riverside South Basin of the Riverside-Arlington Subbasin). As explained under Jurupa CSD, this basin is adjudicated and its groundwater management is "currently the responsibility of WMWD and all groundwater extractors within the basin." (RCSD UWMP, page 23) The RCSD's UWMP (page 12) reports all water users in Rubidoux use this groundwater source. RCSD currently does not purchase or otherwise obtain water from a wholesale water supplier and recycled water is not currently available to the district. The UWMP notes that RCSD expects that groundwater extracted from the Riverside South Basin by its six potable and six non-potable (irrigation only) groundwater wells will "continue to be its primary (and possibly only) source of water through the year 2035 and possibly beyond."

RCSD has approximately 60 miles of pipeline, 11 active production wells (six potable water and five non-potable water), four storage reservoirs and two booster stations. According to 2004 data presented in the LAFCO report, RCSD's retail water system serves a peak demand of 10.0 MGD with a peak capacity of 12.5 MGD and one-day storage capacity. Also according to LAFCO, in 2004 RCSD's existing retail water demand was 5,800 AF and existing supply 10,600 AF. At that time, future (2025) retail water demand was projected at 10,600 AF and future supply RCSD planned to serve was 19,400 AF. The average daily water use for retail customers is approximately 10.8 AF or 3.5 million gallons.

Footnotes:
1. All data from RCSD UWMP, unless noted otherwise. All data rounded to nearest hundred
2. Per UWMP Table 18, water years used (average, dry and multi-year dry): 2001, 2007 and 2007-2009.
3. Value is for system losses (UWMP, Table 7). No groundwater recharge or recycled water used by RCSD.
4. Past (2010) and projected (2015-2035) sales to other agencies (i.e., Jurupa CSD).
5. Actual amounts pumped/used per UWMP Tables 10 and 11.
6. Total supply available is RCSD's current maximum production capability. However, actual amounts pumped would only be as needed to meet actual demand.
7. Per UWMP, page 34, "The district will develop additional groundwater extraction and groundwater treatment facilities as needed to ensure a continuous and adequate water supply for its service area."

Source: RCSD, 2010 UWMP, 2010.

RCSD also has wastewater facilities that consist of regional conveyance facilities, gravity sewers, lift stations and approximately 80 miles of wastewater collection lines. As of 2004, RCSD had approximately 6,000 wastewater service connections. Since the 1970s, RCSD no longer conducts wastewater treatment itself. At present, all wastewater from the service area is conveyed to the City of Riverside for treatment at the Riverside Regional Water Quality Control Plant, which is owned and operated by Riverside and provides tertiary water treatment. This plant's capacity as of 2010 was 40 mgd (approximately 123 AF per day), with expansion proposed.

RCSD currently has capacity rights in the treatment plant for average daily wastewater flows of 3.0 MGD. The volume of wastewater treated as of 2004 was approximately 2.0 MGD. In 2010, RCSD reports 2,230 AF of wastewater was treated. Into the future, the district projects quantities of 2,370 AFY (2015), 2,420 AFY (2020), 2,460 (2025), 2,500 (2030) and 2,550 (2035). All treatment plant effluent is treated to be used for irrigation or is discharged to the Santa Ana River. Recycled water from this plant is not readily available for use by RCSD and, due to economic constraints, no plans to utilize this water are currently proposed or anticipated over the next 25 years.

c. RCSD Water Availability

As shown in Table 4.19-AP (RCSD Water Supply and Demand Summary), the RCSD estimates an available groundwater supply of 14,000 AFY (potable) and 3,000 AFY of non-potable water. These estimates are based on

the "maximum quantity of water that the district is capable of producing if all existing wells operated continuously for 24 hours per day." (RCSD UWMP, page 32) It further notes that the district has "not experienced an actual supply deficiency during dry years, and supply and demand remain relatively unchanged in the district's service area during dry years." This combined with the relatively small amounts of future development anticipated in the district lead the RCSD to plan for relatively stable water supply and demand needs, with growth increases in demand being readily met by the district's existing surplus pumping ability. As indicated by the data above, RCSD has sufficient water supplies and infrastructure to serve both its existing and projected water and wastewater (sewer) needs.

G. Water Providers in Eastern Riverside County

As noted previously, a variety of water providers serve eastern Riverside County, particularly within Coachella Valley. Of these providers, two are State Water Contractors: the Coachella Valley Water District, which imports water from both the Colorado River and (indirectly via MWD) the SWP, and the Desert Water Agency, which also (indirectly) imports SWP water. The Palo Verde Irrigation District (PVID) also uses water from the Colorado River, but only for irrigation purposes; it does not supply municipal (drinking) water. Potable water used in the far east desert region of unincorporated Riverside County comes from local groundwater either through private wells, a mutual water company (shared private system) or through arrangement with the City of Blythe. See discussion in Section 4.19.4-B for more information on groundwater supplies.

In this section, eastern Riverside County providers are summarized, with expanded details provided for CVWD, in particular, as the region's major wholesaler. City water districts are not described in any great detail as they serve incorporated cities only or predominantly.

1. Coachella Valley Water District

Coachella Valley Water District (CVWD), encompassing 995 square miles, extends from San Gorgonio Pass to the Salton Sea. The District provides water to approximately 366,500 residents, in addition to irrigated farmland and a variety of commercial, resort and industrial users. Services provided by CVWD include the delivery of domestic and irrigation water, water conservation, wastewater reclamation and recycling, stormwater protection, agricultural drainage, groundwater recharge and water education. The management and implementation of CVWD water resources are conducted pursuant to its 2010 Urban Water Management Plan Final Report, dated July 2010 ('UWMP' for this subsection).

a. Notes on CVWD

For water management purposes the valley is divided into west valley and east valley regions. The West valley region, which includes the cities of Palm Springs, Cathedral City, Rancho Mirage, Indian Wells and Palm Desert, has a predominantly resort and recreation-based economy that relies on groundwater as its principal water source. The east valley, which includes the cities of Coachella, Indio and La Quinta, as well as the unincorporated communities of Mecca and Thermal, has a more agricultural-based economy relying on both groundwater and Colorado River water imported via the Coachella Canal. The CVWD service area also includes the western and eastern shores of the Salton Sea which relies on groundwater pumped from the Whitewater River Subbasin. See Figure 4.19.25 (CVWD Service Area) and Figure 4.19.26 (Colorado River Water Users and Infrastructure).

Figure 4.19.26

COLORADO RIVER USERS AND INFRASTRUCTURE

This page intentionally left blank.

Nearly all of the Colorado River Hydrologic Region, in which the CVWD is located, has a subtropical desert climate with hot summers and mostly mild winters, and the average annual rainfall is quite low. Average annual precipitation ranges from three to six inches, most of which occurs in the winter. However, summer storms do occur and can be significant in some years. Clear and sunny conditions typically prevail, with the region receiving sunshine 85-90% of each year, the highest value in the United States. Winter maximum temperatures are mild, but summer temperatures are very hot, with more than 100 days over 100° F each year. As an indicator of climate in the Coachella Valley, Palm Springs has an average 24-hour temperature of 73° F.

With the rapid population increase in the Coachella Valley in the early 2000s, the valley's population increased by 35% since 2000. Since late 2007, however, Riverside County has been negatively affected by the current economic recession and some areas have experienced high rates of foreclosures and unemployment. Due to this economic downturn, growth in Riverside County has significantly moderated over the last two years. The RCP-06 growth forecasts were developed and adopted in late 2006 and early 2007, before the onset of the widespread recession. Therefore, the slowdown in the housing market, which was one of the primary components of the recession, is not accounted for in the RCP-06 forecasts. As a result of the recession, economists have predicted slower growth between 2010 and 2015, which could result in a lower than projected (i.e., RCP-06) growth rate for the valley in the near term. The timing and extent of this reduced growth rate cannot be accurately predicted at this time. Nevertheless, because the UWMP planning period extends through 2035, CVWD states that it expects the effect of the recession on growth in the valley to be attenuated over the long term. Changes in the growth forecast will be reflected in future UWMP updates, but to be conservative (overestimating growth and hence water demand), it is assumed that the RCP-06 growth forecasts are applicable.

b. CVWD Water Supplies

CVWD relies on a combination of local groundwater, Colorado River water, SWP exchange water, surface water and recycled water to meet water demands. For its urban water supply, CVWD does not rely on a wholesale water agency; rather, it draws 100% of its supply from local groundwater, a portion of which is replenished from imported water. For imported water, CVWD is a contractor with the United States to receive Colorado River water and both CVWD and DWA are contractors with the State of California to receive SWP water. See Table 4.19-AS (CVWD Water Supply and Demand Summary). The information below discusses these sources, with an emphasis on groundwater. Additional discussions of SWP and Colorado River waters are provided in prior parts

of Section 4.19.3, above. Also, though a State Water Contractor, the CVWD does not currently sell water to other agencies.

The only direct water source for urban water use in the Coachella Valley is local groundwater. Although SWP Exchange and Colorado River water are used to replenish the groundwater basin, the potable water distribution system does not currently receive water directly from either imported water source. Recycled water, as discussed later in this section, is also used extensively by non-potable water customers for irrigation purposes to offset groundwater pumping, but it is not used to offset the demand of urban potable water customers.

Source: Riverside LAFCO, Water and Wastewater Municipal Service Review Report: Western Riverside County and Coachella Valley, 2005.

The urban water distribution system is defined as the area served by CVWD's potable groundwater production wells. CVWD has non-potable irrigation customers who only receive untreated Colorado River water via a

separate irrigation distribution system (the Coachella Canal) that was installed by the United States Bureau of Reclamation in the 1950s primarily for agricultural irrigation. Prior to receiving Colorado River water, these users obtained groundwater from private wells. CVWD plans to install infrastructure to allow its urban water customers to obtain Colorado River water in the future as development occurs. This will include both non-potable Colorado River water for landscape irrigation purposes and treated Colorado River water for potable use. CVWD's non-urban customers may also potentially receive desalinated irrigation drain water and recycled water in the future. These two potential urban water sources are also discussed briefly, below.

(1) Groundwater

As shown in Figure 4.19.14, groundwater is the principal source of municipal water supply in the Coachella Valley. CVWD obtains groundwater from both Whitewater River and the Mission Creek subbasins. The Whitewater River Subbasin is a common groundwater source, which is shared by CVWD, Desert Water Agency (DWA), Myoma Dunes Mutual Water Company (Myoma), the cities of Indio and Coachella, and numerous private groundwater producers. For purposes of administering a replenishment assessment, CVWD divides the Whitewater River Subbasin into the Upper and Lower Whitewater River 'Areas of Benefit' (AOBs). Myoma Dunes and the cities of Indio and Coachella obtain water from the Lower Whitewater River AOB. The Mission Creek Subbasin is also a common water supply that is utilized by CVWD, Mission Springs Water District and private groundwater producers.

Both CVWD and DWA have legal authority (under the 1992 CVWD-DWA Water Management Agreement) to manage the groundwater basins within their respective service areas. Subject to certain legal requirements, each agency may levy an assessment on groundwater pumping to finance the acquisition of imported and recycled water supplies and to recharge the groundwater basins. Towards this end, CVWD has prepared a water management plan (CVWMP, herein) for the Whitewater River Subbasin (7-21.01) and is currently preparing one for the Mission Creek groundwater basin (7-21.02). For details on the legal basis for the water rights involved with these basins, as well as other contractual water rights used by CVWD, refer to the 1992 CVWD-DWA Water Management Agreement.

The Whitewater River Subbasin is not adjudicated. For oversight purposes, it is divided into two management areas, the Upper and Lower Whitewater River Subbasin AOBs. The Upper Whitewater River Subbasin AOB is jointly managed by CVWD and DWA under the terms of the 1976 Water Management Agreement, while the Lower Subbasin AOB is managed only by CVWD. DWA and CVWD jointly operate groundwater replenishment programs wherein groundwater pumpers within designated areas of benefit pay a per-acre-foot charge that is used to fund water importation and aquifer recharge. The Whitewater River Subbasin is further divided into the Palm Springs, Thermal, Thousand Palms and the Oasis subareas.

In 1964, the DWR estimated that the Coachella Valley groundwater basin contained a total of approximately 39.2 million AF of water in the first 1,000 feet below the ground surface; much of this water originated as runoff from the adjacent mountains. Of this amount, approximately 28.8 million AF of water was stored in the Whitewater River Subbasin. However, the amount of water in the subbasin has decreased over the years due to pumping to serve urban, rural and agricultural development in the Coachella Valley that has withdrawn water at a rate faster than its rate of recharge.

Historical fluctuations of groundwater levels within the Whitewater River Subbasin indicate a steady decline in the levels throughout the subbasin prior to 1949. With the importation of Colorado River water from the Coachella Canal after 1949, the demand on the groundwater basin declined in the east valley and the groundwater levels rose sharply. However, since the early 1980s, water levels in this area have again declined, at least partly due to increasing urbanization and groundwater usage. Recharge activities with SWP exchange water began in 1973 at the

Whitewater River Recharge Facility, though activities there have varied depending on SWP exchange water availability. Although the recharge activities have led to stabilization of the groundwater levels near the recharge basins, water levels in the areas of Palm Desert and southerly have generally declined.

2. Population per CVWD 2010 UWMP, Table 2-4.
3. Water years used (for average, dry and multi-year dry benchmarks): 2004-2009, 1977 and 1990-1992.
4. Treated and untreated Colorado River water and (for 2035) 10,000 AF of desalinated agricultural drain water.
5. Potable water only. CVWD also supplies non-potable water for use and for groundwater recharge.
6. Due to its 3a priority, CVWD reports that its Colorado River supplies would generally be unaffected by drought. Similarly, it states the "vast storage capacity of the Whitewater River subbasin (about 28.8 million AF) would be more than adequate to meet the projected groundwater extraction needs of CVWD, DWA and the private pumpers" (even if MWD depletes the Advance Delivery Storage account water). CVWD 2010 UWMP, page 5-8.

(2) Imported Water

In the west valley, resort and urban development typically rely solely on groundwater. Recognizing the need for additional water supplies, DWA and CVWD entered separate agreements for SWP water in the 1960s. To avoid the $150 million cost to construct a pipeline, CVWD and DWA instead signed a water exchange agreement with MWD to deliver an equivalent amount of Colorado River water from MWD's aqueduct in exchange for CVWD's and DWA's SWP water. Groundwater recharge began in 1973 and nearby groundwater levels began to improve, but a steady decline continued in central portions of the valley. CVWD and DWA signed an agreement with MWD for MWD to store excess Colorado River water in the West Valley basin, but even with this additional water, groundwater levels in the west valley continued to decline. With these challenges in mind, the 2010 Coachella Valley MWP sets objectives for meeting all current and future water demands with a 10% supply

buffer, eliminating long-term groundwater overdraft and managing water quality, while managing costs and minimizing adverse environmental impacts.

Also relative to CVWD water supplies, the Quantification Settlement Agreement (QSA) was signed in 2003 and provided assurances regarding existing water sources and additional supplies for CVWD. For additional information and analyses regarding the factors affecting the QSA, please refer to the discussion above regarding MWD's Colorado River supplies in Section 4.19.3. In addition, CVWD and DWA purchase additional SWP water and municipal wastewater treatment plant recycling now contributes approximately 14,000 AFY. Several source substitutions have been successful, with canal or recycled water being used for golf courses in lieu of groundwater pumping and agreements with several developers for use of non-potable water systems for landscape irrigation. Groundwater recharge efforts also continued.

Colorado River Supplies: Colorado River water has been a major source of supply for the Coachella Valley since 1949 with the completion of the Coachella Canal. As discussed in detail above, the Colorado River is managed and operated in accordance with the Law of the River, under which California's apportionment of Colorado River water in a normal year is 4.4 million AFY, which is allocated between Palo Verde Irrigation District (PVID), Imperial Irrigation District (IID), CVWD and MWD, with CVWD and IID in the third priority position. CVWD receives its Colorado River water from the 122-mile Coachella Canal, a branch of the All-American Canal that brings Colorado River water into the Imperial and Coachella Valleys and terminates in CVWD's Lake Cahuilla. See Figure 4.19.26. The service area for Colorado River water delivery under CVWD's contract with the U.S. Reclamation Bureau is defined as Improvement District No. 1, which encompasses most of the east valley and a portion of the west valley north of Interstate 10.

As of 2010, CVWD receives 368,000 AFY of Colorado River water deliveries under the QSA. CVWD's allocation will increase to 459,000 AFY by 2026 and remain at that level for the 75-year term of the QSA. After deducting conveyance and distribution losses, approximately 428,000 AFY will be available for CVWD use. The Colorado River's supply and water quality problems, as well as the ongoing QSA litigation, are discussed in Section 4.19.3.

SWP Supplies: CVWD and DWA also have contractual access to SWP Table A water, as shown in Table 4.19-AS (also see Table 4.19-H). However, there are no physical facilities to deliver SWP water to the Coachella Valley. Thus, CVWD's and DWA's Table A water is exchanged with MWD for a like amount of Colorado River water from MWD's Colorado River Aqueduct. SWP Exchange water has been used to recharge the Whitewater River Subbasin at the Whitewater River Recharge Facility since 1973. MWD, DWA and CVWD executed an advanced delivery agreement in 1985 that allowed MWD to pre-deliver up to 600,000 AF of SWP water into the Coachella Valley. MWD then has the option to deliver CVWD's and DWA's SWP allocation either from the CRA or from water previously stored in the basin. This agreement was subsequently amended to increase the pre-delivery amount to a maximum of 800,000 AF. The 2002 WMP established a goal of maintaining an average amount of SWP exchange water recharge at 140,000 AFY in the Whitewater River Subbasin.

MWD historically has not made full use of its SWP Table A amounts in normal and wet years. Under the 2003 Exchange Agreement, CVWD and DWA acquired 100,000 AFY of MWD's SWP Table A water as a permanent transfer. The water would be exchanged for Colorado River water and either recharged at the existing Whitewater Spreading Facility or delivered via the Coachella Canal for golf course irrigation purposes in the Palm Desert-Rancho Mirage area of the west valley. The transferred water may also be delivered from MWD's Advance Storage account. The terms of the agreement provide that CVWD receives 88,100 AFY and DWA receives 11,900 AFY of MWD's SWP Table A water. CVWD and DWA assume all capital costs associated with capacity in the California Aqueduct to transport this water and variable costs to deliver the water to Lake Perris. MWD retains other rights associated with the transferred water including interruptible water service, carryover

storage in San Luis Reservoir and flexible storage at Castaic and Perris Reservoirs. Amendments to CVWD's and DWA's SWP contracts were executed in 2003. MWD has the option to call back the water in certain years according to specified terms.

In 2004, CVWD purchased an additional 9,900 AFY of SWP Table A water from the Tulare Lake Basin Water Storage District (Tulare Lake Basin) in Kings County. In 2007, CVWD and DWA made a second purchase of Table A SWP water from Tulare Lake Basin totaling 7,000 AFY (DWR, 2007a and 2007b). Also in 2007, CVWD and DWA completed the transfer of 16,000 AFY of Table A water from the Berrenda Mesa Water District in Kern County. These latter two transfers became effective in January 2010. With these additional transfers, the total SWP Table A amount for CVWD and DWA is 194,100 AFY, with CVWD's portion equal to 138,350 AFY.

As further described in the sections above, DWR issues its SWP Delivery Reliability Report every two years. The 2009 Report expressly accounts for impacts to water delivery reliability associated with climate change and recent environmental, legal and regulatory restrictions related to endangered species in the Delta. Based on information from DWR's 2009 Report, the average long-term reliability of SWP Table A deliveries is projected to be 60% of Table A allotments. This allocation percentage is based on computer modeling of the state's watersheds, an expected range of Delta export controls to protect threatened and endangered species, the current condition of the river and reservoir systems, and a variety of potential climate change scenarios. The published reliability of the SWP water has decreased over time, for the reasons discussed above. To account for additional variability related to future SWP supplies, the 2010 UWMP takes the extraordinarily conservative step of further reducing the projected long-term reliability of SWP supplies to 50% of Table A allotments in the absence of successful completion of the Bay-Delta Conservation Plan (BDCP) and delta conveyance facilities.

As per above, CVWD and DWA SWP Table A amounts are used to replenish the Upper Whitewater River and Mission Creek subbasins. Water for recharge is allocated to each in proportion to their levels of pumping. CVWD and DWA both have made significant progress toward meeting the 2002 WMP goal of 140,000 AFY average SWP delivery for the Whitewater River Subbasin.

Table 4.19-AT: State Water Project Supplies to Desert Region

Agency	Original SWP Table A	Tulare Lake Basin Transfer #1	Tulare Lake Basin Transfer #2	MWD Transfer	Berrenda Mesa Transfer	Totals*
CVWD	23,100	9,900	5,250	88,100	12,000	138,350
DWA	38,100	----	1,750	11,900	4,000	55,750
Totals	***61,200***	***9,900***	***7,000***	***100,000***	***16,000***	***194,100***

*All values expressed in AFY. 'SWP' denotes State Water Project.
Source: CVWD, Coachella Valley Water Management Plan, Table 4-3, 2010.

(3) Surface Water

Surface water supplies come from several local rivers and streams including the Whitewater River, Snow Creek, Falls Creek and Chino Creek, as well as a number of smaller creeks and washes. Some of this water is diverted for direct delivery to customers while the remainder becomes part of the groundwater supply through percolation of runoff. In 2009, surface water supplied less than 1% of total water supply to the west valley to meet urban and golf course demands and none to the east valley.

Because surface water supplies are affected by variations in annual precipitation, the annual supply is highly variable. Since 1936, the historical surface water deliveries have ranged from approximately 1,400 to 9,000 AFY, averaging about 5,800 AFY. The majority of local surface water is derived from runoff from the San Bernardino and San Jacinto Mountains with lesser amounts from the Santa Rosa Mountains. This runoff either percolates in the streambeds or is captured in mountain-front debris basins where it recharges the groundwater basin.

According to the estimates developed for the 2010 UWMP Update, since 1993, an average of approximately 60,000 AFY of surface water recharged the Whitewater River Subbasin.

(4) Recycled Water

Recycled water is a significant potential local resource that can be used to help reduce overdraft. Wastewater that has been highly treated and disinfected can be reused for landscape irrigation and other purposes; however, treated wastewater is not suitable for direct potable use. Recycled wastewater has historically been used for irrigation of golf courses and municipal landscaping in the Coachella Valley. In addition, fish farm effluent is available in localized areas of the east valley and a portion is recycled. Based on data from CVWD and DWA, recycled water usage in the west valley is approximately 12,400 AFY (8,200 AFY CVWD usage, 4,200 AFY DWA usage). Recycled water usage in the east valley is approximately 700 AFY and is mainly for agricultural irrigation.

CVWD operates six water reclamation plants (WRPs), three of which generate recycled water for irrigation of golf courses and large landscaped areas. WRP-4 became operational in 1986 and serves communities from La Quinta to Mecca. WRP-4 effluent is not currently recycled; however, it will be recycled in the future when the demand for recycled water develops and tertiary treatment is constructed. The City of Palm Springs operates the Palm Springs Wastewater Treatment Plant. DWA provides tertiary treatment to effluent from this plant and delivers recycled water to golf courses and parks in the Palm Springs area. There is also potential for obtaining recycled water from the reclamation plants operated by the City of Coachella and Valley Sanitary District (VSD), but water from these sources is not currently recycled.

CVWD has also worked with a local aquaculture firm to develop water efficiency programs that include water treatment and reuse. Historically, the amount of fish farm effluent recycled in the east valley was approximately 2,000 AFY. However, one of the largest fish farms in the east valley recently terminated operations and is now using their ponds to grow algae that will be used for the production of biofuel. This shift in operations has significantly reduced groundwater pumping as well as essentially eliminated a source of reusable aquaculture effluent. Water users that have used this recycled water will need to convert to Canal water as a supply. Several areas have been approved for Canal water service pending design and construction of facilities. The 2010 UWMP assumes that no aquaculture water is available for future reuse.

(5) Other Supplies

CVWD along with other valley agencies have investigated other water transfer opportunities described below. Since these water transfers are highly variable, they are not accounted for as firm existing supply capacity available to CVWD.

Yuba River Accord Dry-Year Water Purchase Program: In March 2008, CVWD and DWA entered into separate agreements with the DWR for the purchase and conveyance of supplemental SWP water under the Yuba River Accord Dry-Year Water Purchase Program. This program provides dry year supplies through a water purchase agreement between DWR and Yuba County Water Agency (YCWA) as part of the Lower Yuba River Accord (Yuba Accord), which settled long-standing operational and environmental issues over instream flow requirements for the lower Yuba River. Yuba Accord water transfers will include both surface water and groundwater substitution transfers for an estimated total of up to 140,000 AFY. The available water is allocated among participating SWP contractors based on their Table A allotments. It is estimated that CVWD and DWA may be able to purchase up to 4% (5,600 AFY) and 1.3% (1,800 AFY), respectively for a total of 7,400 AFY. The amount of water available for purchase in a given year varies and will be based on DWR's water year classification. These agreements provide for the exchange of these supplies with MWD for Colorado River water

in accordance with existing exchange agreements. CVWD and DWA obtained 1,800 AF in 2008 and 3,500 AF in 2009 from this program.

Rosedale-Rio Bravo Transfer: In 2008, CVWD executed an agreement with Rosedale-Rio Bravo Water Storage District (Rosedale) in Kern County for a one-time transfer of 10,000 AF of banked Kern River flood water that is exportable to CVWD. Per the Rosedale agreement, deliveries to CVWD began in 2008 and were completed by December 31, 2010. Similar transfers could be executed in future years based on water availability.

c. CVWD Supply Projections

Table 4.19-AU (CVWD Current and Projected Water Supplies), below, presents CVWD's projected direct water supply up to 2035 for urban water use. The CVWD assumes for the purposes of these projections, that total water supplies are equal to total urban water demand. Since groundwater is the principal source of water supplies and the groundwater basin is not adjudicated, actual water supply of the basin is dependent on replenishment and production by other water users of the groundwater basin. With the ongoing implementation of the Coachella Valley WMP, it is assumed that CVWD will either reduce or maintain its current groundwater pumping and meet the rest of its demand with Colorado River water. This urban water supply from the Colorado River will gradually increase with time as the required infrastructure is installed and will offset groundwater pumping to meet the urban water demand.

Table 4.19-AU: CVWD Current and Projected Water Supplies

Water Supply Sources (in AFY)	2010	2015	2020	2025	2030	2035
Supplier-Produced Groundwater	109,488	118,700	125,600	129,900	133,500	128,700
Treated Colorado River Water	0	5,700	19,300	31,400	39,500	49,100
Untreated Colorado River Water	0	1,300	11,100	26,300	39,000	54,800
Desalinated Agricultural Drain Water	0	0	0	0	0	10,000
Totals	**109,488**	**125,800**	**156,100**	**187,700**	**212,000**	**242,700**

Source: CVWD, UWMP, Table 4-1, page 4-4, 2010.

d. CVWD Water Supply Issues

The existing water supplies face risks and variability that could affect long-term supply reliability. These include the extended drought in the southwestern United States and legal/regulatory decisions affecting vital contracts and water deliveries. In addition, climate change could impact both supplies and demands in the valley.

Colorado River: Although CVWD's Colorado River supply has historically been fully available, drought conditions affecting the Colorado River and legal issues affecting the QSA may continue to affect the availability and reliability of this supply in the future. Other issues affecting the reliability of Colorado River water supplies are discussed above (see Section 4.19.3).

State Water Project: Many of the issues affecting the availability and reliability of SWP supplies are discussed above (see Section 4.19.3) and in Appendix EIR-8. CVWD and DWA have contractual rights to SWP water, which are exchanged with MWD for an equivalent amount of Colorado River water. While CVWD and DWA do not take any actual delivery of SWP water because of the lack of conveyance facilities, the exchange water amounts will decrease with any decrease in the amount of SWP water in which those agencies have contractual rights. However, current assumptions are that, if successful, these programs could restore average long-term SWP delivery reliability to the pre-Wanger decision levels of 77% of Table A amounts. This assumption is consistent with planning assumptions being made by MWD in its 2010 RUWMP that is discussed in detail above.

Accordingly, the 2010 UWMP evaluates both the conservatively low (50%) and high (77%) reliability in determining future water needs for the valley.

Recycled Water: Recycled wastewater has historically been used for irrigation of golf courses and urban landscaping in the Coachella Valley. The amount of wastewater available for recycling in the future primarily depends on growth in the valley. Future waste discharge requirements will dictate the level of treatment that would be required at the valley's wastewater treatment plants. More stringent discharge requirements might result in higher treatment costs, which in turn might make recycling a more feasible option. Thus, future growth and water quality regulations will dictate the amount of recycled water available in the Coachella Valley.

Water Quality: The Water Quality Control Plan for the Colorado River Basin (Region 7) (Basin Plan) was prepared and adopted by the Colorado River Regional Water Quality Control Board (RWQB) in 1993. The planning area includes the Coachella Valley. The Basin Plan was updated with subsequent amendments and was readopted by the RWQCB in June 2006. The Coachella Valley water agencies will keep tracking proposed changes to the Basin Plan and will actively participate in development of new policies. Additional monitoring, increased treatment and implementation of best management practices (BMPs) can also help limit discharges to the CVSC and Salton Sea which could otherwise conflict with the Basin Plan.

Salinity management is an important water quality issue in the Coachella Valley. Use of imported water for recharge, agricultural irrigation and municipal irrigation directly results in the addition of salt into the basin. Some areas in the valley, such as the Oasis and Salton City, have naturally occurring high-salinity groundwater. If the activities in the basin are not managed properly, the salt could eventually migrate to the Lower aquifer and result in long-term water quality degradation in the groundwater basin. Colorado River water used for delivery and recharge in the Coachella Valley has higher TDS concentrations on average than most local groundwater. CVWD is investigating alternatives to reduce water quality impacts of Colorado River recharge, including direct importation and recharge of lower TDS System Conservation Plan water through construction of an $800 million to $1.5 billion SWP extension. However, this would significantly increase the cost of providing water to Coachella Valley customers and would provide water only for recharge to the west valley. Another alternative is treatment of Colorado River water before recharge. The primary deterrent to this is against cost, because it could increase the annual water bill for an average customer by $450, with an even greater impact on major water users such as golf courses. CVWD will continue to work with other water purveyors to develop a plan for addressing this issue.

Recycled municipal wastewater is being used for irrigation for golf courses, other municipal greenbelts and landscaped areas. Because the amount of municipal wastewater available for reuse is expected to increase 150% by 2045, this water represents a valuable resource that needs to be put to beneficial use to reduce groundwater overdraft. Valley-wide recycled water projects identified in the 2010 WMP Update will be implemented.

Pursuant to SWRCB requirements, a salt/nutrient plan must be developed by 2014, which is intended for management of all sources contributing salt/nutrients on a basin-wide or watershed-wide basis to ensure that water quality objectives are achieved, taking into consideration all sources, hydrogeology, recharge, water quality and other factors. Brine discharge and management will also be a major issue in the Coachella Valley in the future and a detailed study should be conducted to evaluate brine disposal alternatives. CVWD will undertake a detailed study investing alternatives for brine disposal.

Discharges from agricultural lands can affect water quality by transporting pollutants from fields to surface waters. The State and Regional Water Quality Control Boards can conditionally waive waste discharge requirements if it is in the best interest of the public and such waivers are generally given on the condition that the discharges not cause violations of water quality objectives. CVWD's existing waivers for these discharges

have expired; the RWQCB must develop a water quality control policy to address potential or actual impacts of these discharges on the waters of the region

In addition to salinity concerns, current and emerging groundwater quality issues include arsenic, perchlorate, chromimum-6, uranium and nitrates. As of 2006, the standard for maximum arsenic levels is 10 μg/L and arsenic concentrations as high as 162 μg/L have been observed in some east valley municipal water wells and other wells exceeded the standard. Three new groundwater treatment facilities became operational in 2006 and can be expanded to treat additional wells if necessary.

Perchlorate has been found in Colorado River water imported to the Coachella Valley. It originated from the Kerr-McGee plant in Nevada, on Las Vegas Wash upstream of Lake Mead. Use of Colorado River water for irrigation and recharge in the east valley led to perchlorate contamination of the groundwater there. Perchlorate seep capture and treatment was initiated in 1999 and three locations in Nevada, which has resulted in significant reduction in Colorado River contamination. Tests on CVWD groundwater wells in 2000 and 2009 showed no detectable perchlorate and DWA detected only levels of perchlorate below the maximum contaminant limit (MCL). Monitoring will continue. No wells in the Coachella Valley exceed the 50 μg/L total chromium MCL. Monitoring will continue. While trace uranium levels have been observed in groundwater in the Cove communities and Indio Hills system, they were well below the California MCL. Monitoring will continue.

The primary drinking water standard for nitrates is 10 mg/L and concentrations as high as 40 mg/L have been found in some of the shallower portions of the Coachella Valley groundwater basin. Steps have been identified to reduce the risk of nitrate migration, including locating recharge activities away from areas of high nitrate concentrations and treatment of pumped groundwater.

Invasive Species: The non-mollusk known as the Quagga mussel has been found in the Colorado River system, which could significantly affect Coachella Valley's water quality, aquatic ecosystems and water delivery systems. Quagga mussels were first discovered in Lake Mead in January 2007 and have infested the CRA by way of Lake Havasu. They have been found at Imperial Dam, but have not been detected in the Coachella Canal. CVWD has been proactively working to prevent infestation and spread by chlorinating Coachella Canal water downstream of the turnout from the All-American Canal and turbulence is generated by keeping the gate partially closed.

Subsidence: Declining groundwater levels can contribute to or induce land subsidence in aquifer systems that contain a significant fraction of silts and clays. Land subsidence can disrupt surface drainage, cause earth fissures and damage wells, buildings, roads and utility infrastructure. Since the late 1970s, demand for water in the east valley has exceeded the deliveries of imported surface water, pumping increase and groundwater levels declined. At least four areas in the Coachella Valley have experienced land subsidence between 2003 and 2005, and subsidence rates increased by as much as a factor of 10 between 2000 and 2005. However, studies of these sites have not confirmed a relationship between the land subsidence and declining groundwater levels, and the 2002 Coachella Valley Water Management Plan Programmatic EIR incorporated mitigation measures addressing potential land subsidence caused by declining water levels. Valleywide subsidence studies are continuing.

Salton Sea Restoration: The Salton Sea is a saline terminal lake located at the east end of the Coachella Valley. It is California's largest lake and a main stop on the Pacific Flyway for migratory birds. Approximately 90% of the freshwater inflow into the Sea is agricultural drain water from the Imperial, Coachella and Mexicali valleys. Because the Sea has no outlet, salts concentrate in it by evaporation. Salt concentrations in the Sea are currently about 51,000 mg/L, about 45% higher than ocean water, with the salinity increasing another 1% per year. The 2010 UWMP currently plans for existing drain flows into the Salton Sea to remain at current levels. However, in order to meet the 2045 demand conditions in the Coachella Valley, up to 112,000 AFY of drain flow into the

Salton Sea will be captured and desalinated for urban use. This may result in a substantial reduction of projected flow to the Salton Sea from the Coachella Valley compared to previous estimates.

e. CVWD Water Demand Projections

CVWD's UWMP provides a number of tables for past, current and projected urban water usage projections. The District's two biggest water use sectors are single-family homes and landscaping. And, for such residential uses, it is estimated that 80% of a single-family home's water usage is for outdoor landscaping. Accordingly, CVWD has focused its conservation efforts to reduce landscape water usage. Table 4.19-AV (CVWD Total Urban Water Deliveries by Customer Type), below, shows existing and projected urban water use by sector.

Projected water use for 2015 through 2035 in five-year increments is shown in Table 4.19-AW (CVWD Total Projected Potable and Non-Potable Urban Water Use) below. According to the UWMP, these demand projections are based on projected population and per-capita water use. As mentioned earlier, the population projections are based on Riverside County's RCP-06 forecasts. For the projected per-capita water use shown, the baseline population is the current existing service area population. It is then assumed that this population will have a 20% reduction in per-capita water use due to tiered water rates and landscaping conservation (pursuant to SB7x7 mandates, etc.). The added population is composed of future new CVWD customers. These new customers are calculated to have a greater reduction in outdoor per-capita water use due to CVWD's landscape ordinance and other conservation efforts. Based on the currently available development and land use information for Coachella Valley, it is assumed that the proportions of water use by sector in the future will be equal to the sector proportions of 2010 water use.

Table 4.19-AV: CVWD Total Urban Water Deliveries by Customer Type

Year	Units[1]	Single family Resi.	Multi-family Resi.	Commercial	Industrial	Instit./ Gov.	Landscape	Agri.[2]	Construct.	Totals

Footnotes:
1. Includes both metered and unmetered sources, but excludes system water losses. 'Volume' in acre-feet (AF).
2. CVWD serves agricultural farms, golf courses and other uses with Colorado River water via a non-potable distribution system. The volume of agricultural water use is described in Table 3-18 of the UWMP.
3. Values for 2010 are actual. Values for rest of the years are projected estimates.

Source: CVWD, UWMP, Tables 3-8 through 2-12, 2010.

f. CVWD Coachella Valley Water Management Plan Implementation

Implementation flexibility is critical to respond to variable and unpredictable future growth as well as water supply conditions. The 2010 CVWMP Update (CVWMP) identifies water conservation and water supply elements sufficient to meet not only the projected water demands, but to provide a level of contingency should individual water conservation and supply projects not be implemented as currently envisioned or if growth is higher than

anticipated. If these objectives are not met, then additional measures must be implemented. For example, the amount of future water conservation, water transfers and drain water desalination can be adjusted in response to the outcome of long-term solutions in the Delta. Once water conservation and supplies are defined, water management strategies can be developed to reduce and ultimately eliminate groundwater overdraft. The two primary measures for doing this are source substitution and groundwater recharge. Again, a flexible approach is taken where targets for both source substitution and recharge are established.

Table 4.19-AW: CVWD Total Projected Potable and Non-Potable Urban Water Use

Water Use (in AFY)	2010	2015	2020	2025	2030	2035
Total Urban Consumptive Water Uses[1]						
Single-family Residential	59,900	69,900	86,700	104,300	117,800	134,800

Footnotes:
1. Consumptive water uses exclude system water losses.
2. Industrial water delivery is zero (per CVWD, 2010 UWMP, Tables 3-9 through 3-12) and therefore omitted.
3. CVWD serves agricultural uses with non-potable water from the Colorado River. Thus, it is included under 'Non-potable Water Use,' rather than in this category.
4. Values for 2010 based on anticipated operations. Actual values may be higher based on imported water availability. Values for 2015 through 2035 represent average annual values based on anticipated water availability.
5. Values are estimated. Site of the recharge facility in Indio is still under investigation.
6. Water recharged at Whitewater and Mission Creek facilities is the joint responsibilities of CVWD and DWA. Amounts will vary based on hydrologic conditions and amount of groundwater pumping conducted.
7. Golf course and municipal non-potable demand is use of recycled water and Canal water.
8. Future system water loss is assumed to be 3.2% of total water production, which is the average system water loss percentage from the past five years (i.e., 2006-2010).

Source: CVWD, UWMP, Tables 3-9 through 3-12 and Tables 3-17 through 3-20, pages 3-7 through 3-15, 2010.

However, these targets are flexible to allow adjustments in response to changes in development patterns affecting sources substitution and basin groundwater levels. Source substitution programs initially focus on supplying imported and recycled water to existing groundwater users. As growth occurs, these systems can be used to meet the needs of future development without increasing groundwater use. Recharge projects provide flexibility by allowing variable amounts of recharge in the future to either restore storage losses during dry periods and to prevent excessively groundwater levels.

The elements of the CVWMP implementation plan are being carried out by CVWD in conjunction with the region's Indian Tribes and other valley water districts. (See Appendix EIR-8 for copy of the CVWMP implementation plan, i.e., Table 8-1 of that document.) The plan calls for completion of key measures between

2010 and 2020. The central themes of these elements are balance and flexibility, with the minimization of costs as feasible. Currently, due to groundwater overdraft and full use of existing developed supplies, there is no supply buffer. Development of the additional supplies to provide a buffer may also provide an opportunity to reduce overdraft earlier and store water in the basin for future use. Under the implementation plan, a supply buffer will be achieved by establishing increased planning targets for urban water conservation, desalinated drain water, recycled water and water transfers and taking the actions to implement these higher targets, if and when needed. Pursuant to the plan, in 2011 the supply buffer should be about 68,000 AFY and should gradually increase with demand until a buffer of around 89,000 AFY is achieved by 2045.

Based on the water conservation measures described in the programs below, the range of potential savings to be achieved will be 43,000-100,000 AFY for urban water uses, 11,000-23,000 AFY for agricultural water use and 6,000-22,000 AFY for golf courses. This translates into a total savings of between 60,000-145,000 AF per year.

(1) Urban Conservation

Although CVWD could likely meet the requirements of SBX7-7 without implementing additional conservation measures, water savings in excess of SBX7-7 requirements are likely due to the significant emphasis placed on reduced water use by existing and future customers. Based on the potential range of domestic water conservation actions identified in the 2010 UWMP, additional urban water conservation savings could potentially range from 43,000 AFY to 266,000 AFY by 2045. Extreme changes in lifestyle would be required to reduce water use to an amount comparable to Tucson (50% reduction) or the Colorado River region's target in the 20x2020 Plan (41% reduction).

Methods available for achieving these targets (i.e., Level 3 option) include the following: Continued implementation of the 2009 Valleywide Landscape Ordinance (Ordinance No. 1302-2); installation of automated or 'smart' water meters; extension of the landscape ordinance to include all landscaping regardless of size (current limit is 5,000 square-feet or larger for homeowner furnished landscaping); implementation of water budget-based tiered water rates or other conservation based rates by other water agencies; further decreases in the water allocations for landscape irrigation consistent with good irrigation practices and desert landscaping; the offering of landscape retrofit rebates, i.e., economic incentives for replacing high water use landscaping with water-efficient vegetation, also known as "cash for grass;" placing of restrictions on the total amount of turf allowed; mandating use of smart irrigation controllers by all customers; performing audits of new development to assure continued compliance with the landscape ordinance; requiring plumbing retrofits for existing properties, including mandatory retrofit (ultra-low flush toilets, showerhead replacement, etc.) prior to sale of property; offering conservation rebates for high-efficiency clothes washers; complying with 2009 California Green Building Code standards (CCR, Title 24, Part 11); and, performing water distribution system audits and implementing loss reduction programs.

(2) Agricultural Conservation

Agricultural conservation programs have consisted of CVWD funding and voluntary grower participation. Through the "Extraordinary Conservation Program," the CVWD was able to completely payback its water overrun (73,200 AF) by 2009. A cooperative study, "Water 2025," was funded by Reclamation, CVWD and participating growers and suppliers within the Coachella Valley. The objectives of the study were to provide clear quantification of reductions in applied water resulting from specific farm practices and to develop a market mechanism for saved water. The following provides the building blocks for agricultural conservation.

Grower Education and Training: This would consist of grower meetings and grower training programs funded by the District. In order to encourage grower participation, the District would implement confidential grower audits.

District-Provided Services: This would include CVWD-funded conservation programs provided as a service to growers in the district. Programs would include scientific irrigation scheduling, scientific salinity management, moisture monitoring and farm distributions uniformity evaluations. From 2004 through 2009, 73,400 AF of documented extraordinary conservation occurred using these programs for a total program cost of $2,954,000. Additional expenditures of $200,000 in 2009-2010 resulted in savings of 3,400 AFY.

Irrigation Upgrade/Retrofit: This would add full funding, partial funding or financial support to growers that wish to convert from flood and sprinkler to micro-sprinkler and drip systems. In a fully funded program, the CVWD would provide reasonable reimbursement to a grower that upgrades his or her irrigation system or retrofits an aging drip system. A partially funded program would cost-share the expenses and a program that offers financial support would provide low or no-interest loans for the upgrades or retrofits.

Economic Incentives: This would involve adoption of one or more pricing approaches to encourage conservation, if needed. This might be accomplished by establishing an irrigation water allocation based on evapotranspiration (the rate water is lost from plants and the soil into the air) and a crop-specific coefficient. Water use in excess of the base allocation would be charged at a higher rate.

Regulatory Programs: These types of programs would be considered as a last resort and would include regulations that support and provide for agricultural conservation. Programs could include: grower-prepared on-farm water management plans defining the methods of applying water and the water conservation measures utilized; and, all new permanent crops would use drip and/or micro-spray irrigation systems. All current crops must be converted within a five-year period.

Evaluation of grower practices and crop requirements indicates that a savings of up to 14% of current water use could be achieved through incremental implementation of these measures. Assuming no change in cropping patterns and average evapotranspiration conditions, agricultural water use is expected to decrease from 6.2 AFY per acre to about 5.33 AFY per acre. As agricultural land is removed from production in response to urban development, it is expected that the amount of water saved through agricultural conservation will decrease from almost 39,500 AFY in 2020 to 23,000 AFY in 2045. In general, CVWD program experience indicates the cost of agricultural conservation is in the range of $30 to $60/AF of water conserved, making it a very cost-effective method for extending the water supply.

(3) Golf Course Conservation

The CVWD Landscape Ordinance established maximum allowable turf area and associated water demands for new golf courses by limiting turf to four acres per hole plus ten acres for associated practice areas (driving ranges and putting greens). Other landscaping must use low water-using plant materials. Based on a typical 18-hole course encompassing about 125 acres of landscaped area, the expected water use would be about 700 AFY, which is an additional 22% reduction compared with the 2002 WMP goal for new courses. CVWD continues to work with new and existing golf courses to reduce water demands through programs such irrigation system audits, soil moisture monitoring, plan checking, inspecting new golf courses for plan check compliance and monitoring maximum water allowance compliance. Implementation of conservation measures could reduce golf course demands by 11,600 AFY by 2045.

g. CVWD Sewer and Wastewater Treatment Services

CVWD operates six wastewater reclamation plants (WRPs), three of which (plants 7, 9 and 10) currently generate recycled water for irrigation of golf courses and large landscaped areas. WRP-4 serves communities from La Quinta to Mecca, although its effluent is not currently recycled. However, it will be recycled in the future when the demand for recycled water develops and tertiary treatment is constructed. The City of Palm Springs operates the Palm Springs Wastewater Treatment Plant. The DWA provides tertiary treatment to effluent from this plant and delivers recycled water to golf courses and parks in the Palm Springs area. There is also potential for obtaining recycled water from the reclamation plants operated by the City of Coachella and Valley Sanitary District, but water from these sources is not currently recycled. CVWD plans to expand the non-potable water delivery systems described below in the future. The existing wastewater treatment plants treat 35,900 AF annually and with expansions will have a projected treatment capability of just under 89,700 AFY.

Water Reclamation Plant 1 (WRP 1): WRP-1 serves the Bombay Beach community near the Salton Sea. It has a design capacity of 150,000 gallons per day and consists of two mechanically aerated concrete-lined oxidation basins, two unlined stabilization basins and six evaporation-infiltration basins. Currently all of the effluent from this facility is disposed by evaporation-infiltration. CVWD has no plans to recycle effluent from this facility because of the low flow and lack of potential uses near the plant.

Water Reclamation Plant 2 (WRP 2): WRP-2 serves housing in the North Shore community with two types of treatment facilities: an activated sludge treatment plant capable of providing secondary treatment of up to 180,000 gpd and an oxidation treatment basin with a design capacity of 33,000 gpd. The oxidation treatment basin is mechanically aerated and lined with a single synthetic liner. The activated sludge treatment plant is used only when the maximum daily flow exceeds 33,000 gpd, otherwise the oxidation basin is used for treatment. WRP-2 is currently discharging an average of 18,000 gpd of treated secondary effluent into four evaporation-infiltration basins for final disposal. CVWD has no plans to recycle effluent from this facility because of the low flow and lack of potential uses near the plant.

Water Reclamation Plant 4 (WRP 4): CVWD's WRP-4 is a 9.9-million gallons-per-day (mgd) capacity treatment facility located in Thermal. WRP-4 provides secondary treatment consisting of pre-aeration ponds, aeration lagoons, polishing ponds and disinfection. The treated effluent is discharged to the CVSC pursuant to a NPDES permit. Annual average flow to the facility is approximately 4.75 mgd (5,300 AFY). Effluent from WRP-4 is not currently suitable for water recycling due to the lack of tertiary treatment. However, CVWD plans to add tertiary treatment and reuse effluent from this plant in the future as development occurs.

Water Reclamation Plant 7 (WRP 7): Located in northern Indio, WRP-7 is a 5.0-mgd secondary treatment facility with a current tertiary treatment capacity of 2.5 mgd. The tertiary-treated wastewater is used for irrigation of golf courses in the Sun City area. The average annual flow in 2010 is estimated to be 3 mgd (3,300 AFY). The plant consists of aeration basins, circular clarifiers, polishing ponds and filtration. Recycled water not used for irrigation is percolated at onsite and offsite percolation ponds. A plant expansion is currently under design that will increase the plant capacity to 7.5 mgd.

Water Reclamation Plant 9 (WRP 9): Located in Palm Desert, WRP-9 treats approximately 0.33 mgd (370 AFY) of wastewater from the residential development surrounding the Palm Desert Country Club. Treatment units at the plant include: a grit chamber, aeration tanks, secondary clarifiers, chlorine contact chamber, aerobic digester and two infiltration basins. One basin is lined for storage of treated wastewater. Raw wastewater in excess of the design capacity is pumped to WRP-10 for treatment. Secondary effluent from WRP-9 is used to irrigate a portion of the Palm Desert Country Club golf course. During winter months when demand is low, effluent that cannot be recycled is diverted to the infiltration basins for disposal through ground infiltration.

Water Reclamation Plant 10 (WRP 10): WRP-10 is located in Palm Desert and consists of an activated sludge treatment plant, a tertiary wastewater treatment plant, a lined holding basin, six storage basins and 21 infiltration basins. The plant's combined secondary wastewater treatment design capacity 18 mgd. WRP-10 treats an annual average daily flow of 10.8 mgd from the activated sludge plant. Approximately 60% of this plant's effluent receives tertiary treatment for reuse and is delivered to customers through an existing recycled water distribution system. The remaining secondary effluent is piped to a holding basin or one of six storage basins and disposed of by distribution to the 21 infiltration basins. Most of the secondary effluent receives tertiary treatment and is used for irrigation of local golf courses. Since 2009, CVWD blends tertiary effluent with Coachella Canal water provided by the Mid-Valley Pipeline for distribution to golf courses.

h. CVWD Water Availability

The above elements of the 2010 UWMP Update and Implementation Plan avoid excessive reliance on any one supply source while meeting projected water demands in the CVWD service areas. The CVWD's 2010 UWMP Update demonstrates that the total projected water supplies available to CVWD will be sufficient to meet the total projected water demands of their customers during normal, single-dry and multiple dry-year periods, and that successful implementation of planning efforts will result in a 10% supply buffer by the year 2045.

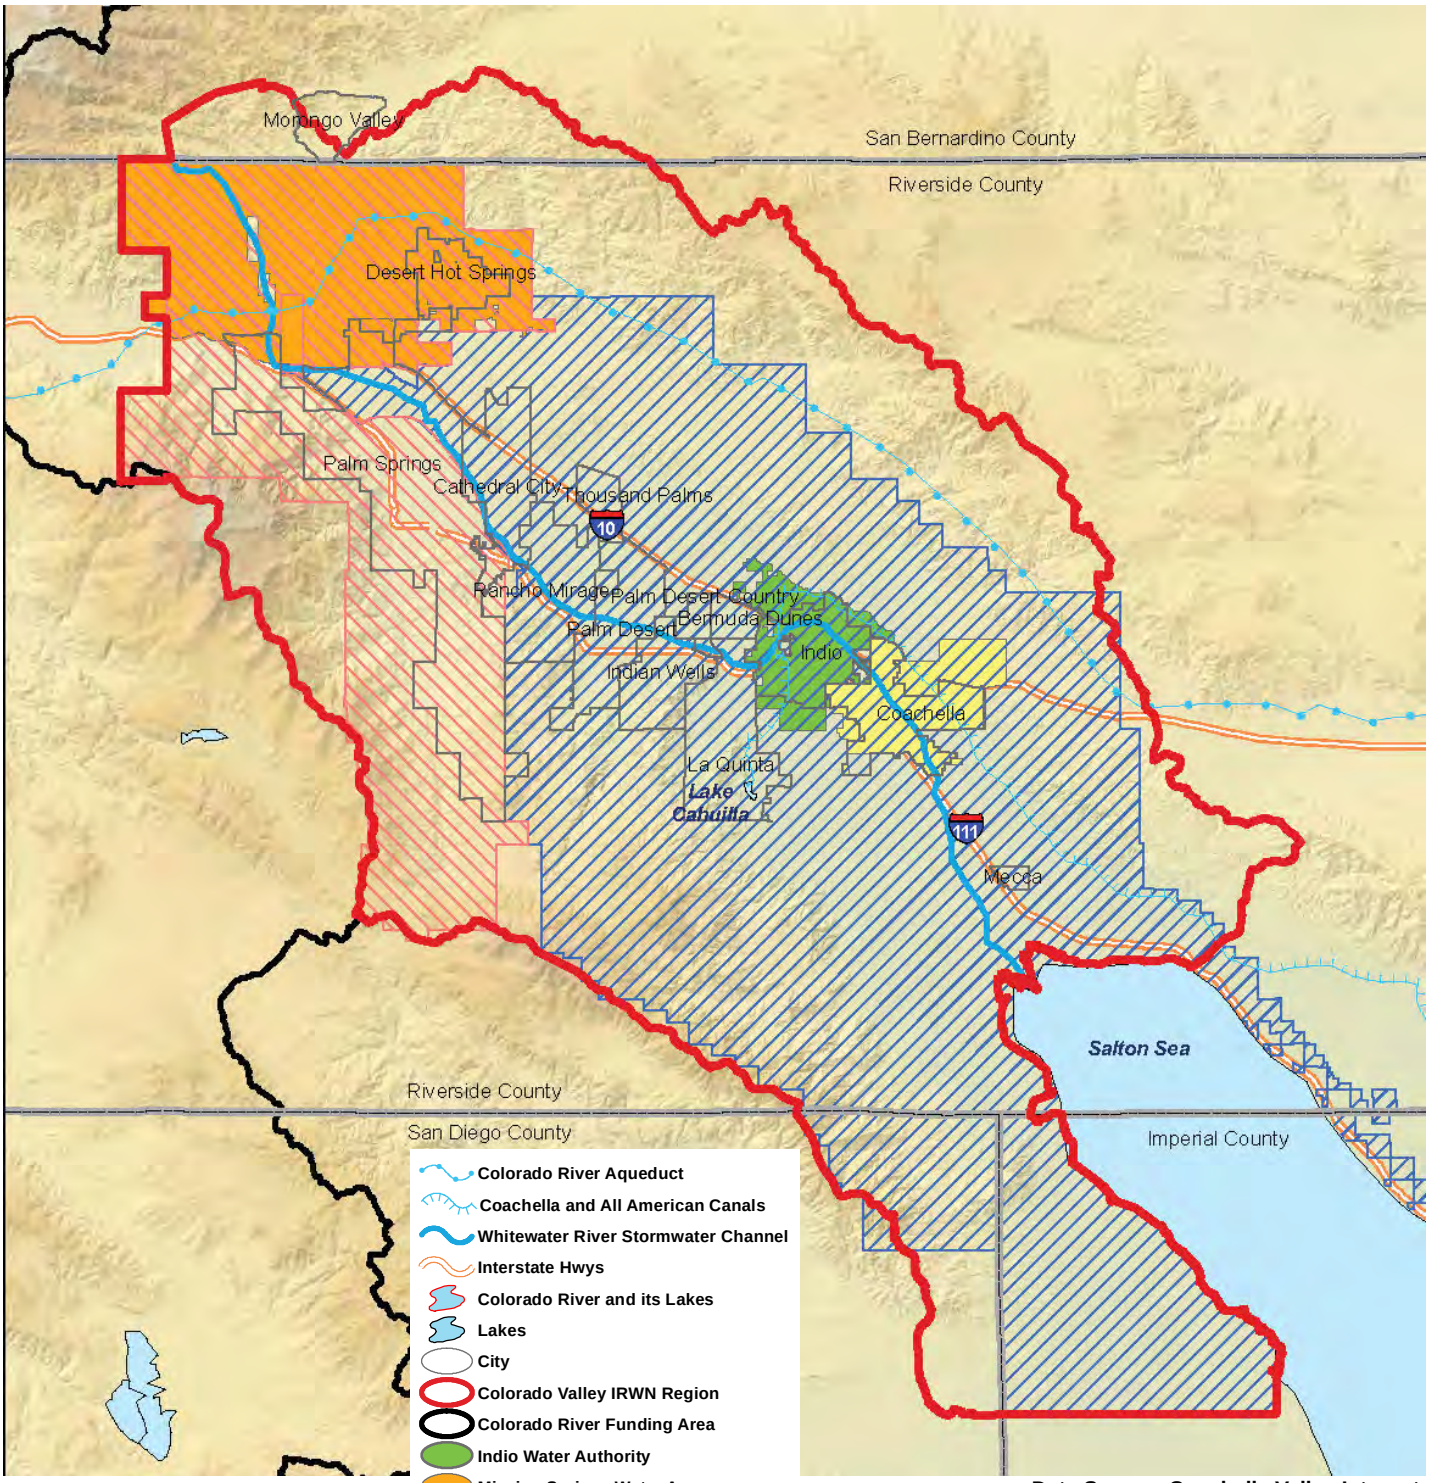
2. Desert Water Agency

Desert Water Agency (DWA), a State Water Contractor, is the water utility for the northwesterly portion of the Upper Coachella Valley. Originally, in the 1920s and 30s, DWA's municipal water supply came entirely from creek diversions. Today, DWA's water supply sources include groundwater produced by local potable water supply wells, surface water diverted from creeks in the San Jacinto Mountains, imported SWP water and recycled water (used for irrigation). All of the imported (SWP) water is used for recharge of the Upper Coachella Valley groundwater basin, particularly the Whitewater River and Mission Creek subbasins. DWA provides both wholesale water to the Missions Springs Water District (MSWD) and potable water to its own retail customers. DWA's 2010 Urban Water Management Plan (UWMP) addresses a variety of issues related to water supply, demand and reliability. Additional information about this water district is provided in Appendix EIR-8.

a. Notes on DWA

The DWA provides municipal (retail) water service to the City of Desert Hot Springs, part of Cathedral City and most of Palm Springs, as well as to outlying county unincorporated areas, for a total area of approximately 335 square miles. See Figure 4.19.27 (Water Agencies in the Coachella Valley). In addition to supplying municipal water, DWA also provides artificial groundwater recharge or replenishment to augment local groundwater supplies using imported water and also makes imported water available to MSWD for groundwater recharge within its service area. It also uses Colorado River water to replenish underground aquifers in cooperation with CVWD and gets additional (surface) water from mountain streams: Chino Creek, Snow Creek and Falls Creek.

Because of the region's low annual rainfall and extremely high summer temperatures, large quantities of water are required for supplemental landscape irrigation, even during the cooler winter months. As a result, DWA estimates up to 80% of water supplied to local customers is used outdoors. Thus, DWA has focused water conservation efforts on developing outdoor water conservation measures.



Data Source: Coachella Valley Integrated Water Management Plan (2009)

December 16, 2013

Figure 4.19.27

WATER AGENCIES IN THE COACHELLA VALLEY

This page intentionally left blank.

DWA's surface water diversions account for 10% of less of its total water supply. Surface waters utilized are from the Whitewater River, as well as several of its tributary creeks. Between 2005-2009, surface water diverted by DWA ranged from between 1,000 to 2,500 AFY. The DWA projects future surface water diversions between 2010-2035 will be 5,900 AFY.

Colorado River water is exchanged for SWP water per 2003 and prior Exchange Agreements among DWA, CVWD and MWD. According to DWA's UWMP (page II-2), currently approximately 93% of exchange water is directed to the Whitewater River Subbasin, of which 25% is allocable to DWA, with the remaining 75% to the CVWD. SWP water consists of DWA's apportionment of its Table A allocation, Article 21 surplus water allocation (when available) and other surplus water acquired and conveyed through the SWP. Other surplus water used for import includes Pools A and B Turnback water, Yuba River Accord water and Central Valley flood water from the Kern and other rivers. See Section 4.19.3 and Appendix EIR-8 for more information on these water sources.

Groundwater extracted by the DWA is the result of natural recharge, non-consumptive return and groundwater from storage. The DWA extracts groundwater for municipal use from the upper portion of the Whitewater River Subbasin, one of the Coachella Valley Groundwater Basin's five subbasins. The supply is supplemented with artificial recharge with imported SWP and Colorado River water according to a complex series of agreements amongst the basin's major users (see the prior section on CVWD for additional discussion).

Due to pumping to serve urban, rural and agricultural development, which has withdrawn water at a rate faster than its rate of discharge, the amount of water in the Whitewater River Subbasin has decreased over the years. The Whitewater River Subbasin is not, however, adjudicated. The DWA does not currently have a groundwater management plan per Assembly Bill 3030, but in 1976, the DWA and CVWD entered into a joint Water Management Agreement (as amended in 1992) for the cooperative management of the Whitewater River Subbasin. Under this agreement, the DWA and CVWD jointly operate groundwater replenishment programs wherein groundwater pumpers within designated areas of benefit pay a per-acre-foot charge that is used to pay the cost of importing water and recharging the aquifer. See Section 4.19.E-1 (CVWD discussion) for additional details on the Whitewater River Subbasin.

Table 4.19-AX: Desert Water Agency Background Information

Sub-Agencies Served[1]			**Cities and Communities Served[2]**		
Mission Springs Water District			City of Palm Springs		Cathedral City
Palo Verde Irrigation District			City of Desert Hot Springs		
Service Area Statistics[3]					
Size	214,400 acres		***CA Hydrologic Region***	Colorado River	
Population	60,600 people		***Regional WQCB***	7 – Colorado River

	X	Retail Water		_	Desalination
	X	Recycled or Non-Pot. Water		X	Groundwater Recharge
	X	Wastewater (Collection)		X	Wastewater Treatment

Footnotes:
1. Unless noted otherwise, the District provides wholesale water to these sub-agencies.
2. City/community may be served by this district either wholly or partially. Areas in which only a small fragment are served by the water district or are outside of the district's formal service area may be omitted for clarity.
3. Services and service area statistics from Riverside LAFCO, 2005 Water and Wastewater Municipal Service Review.
4. Only facilities operated directly by the listed water agency included.

Source: DWA, UWMP, Dec. 2011. Riverside LAFCO, Water and Wastewater Municipal Service Review Report, 2005.

Except for DWA's surface water diversions, all water produced within the Whitewater River Subbasin is groundwater. Per page II-4 of their UWMP, extracted groundwater provided between 81-95% of the water served

by DWA. Between 2010 and 2035, this trend is projected to continue with groundwater providing between 78-81% of the total water supplies provided by DWA.

Based on the above information, the various contracts and agreements in place and other factors presented in its UWMP (page II-7), the DWA finds that, "The Whitewater River and Mission Creek subbasins are capable of meeting the demands that will be placed on them, provided they continue to be replenished with sufficient quantities of imported water to meet future needs."

3. New facility if no 'current' data listed; otherwise additional capacity or treatment process upgrade indicated.
4. DWA's RWTF provides tertiary treatment once the City of Palm Springs has completed primary and secondary treatment per 1988 agreement.

Source: Riverside LAFCO, Water and Wastewater Municipal Service Review Report: Western Riverside County and Coachella Valley, 2005.

In 1988, DWA and the City of Palm Springs entered into an agreement to treat wastewater. Under this agreement, the city provides primary and secondary treatment then the secondary effluent is piped to DWA's Recycled Water Treatment Facility (RWTF) for tertiary treatment. The RWTF has a present treatment capacity of 10.0 million gallons per day (MGD) with an ultimate capacity of 15.0 MGD. The facility provides recycled water for landscape irrigation use by its customers. Any excess secondary effluent is discharged into percolation ponds for groundwater recharge. DWA projects use of 7,900 AFY of recycled water (a combination of tertiary treated water used for landscape and secondary treated water for groundwater recharge) in 2010, increasing to 11,000 AFY by 2035.

b. DWA Water Availability

The existing water supplies face risks, variations and unpredictability that could affect long-term supply reliability. These include the extended drought in the southwestern United States and legal/regulatory decisions affecting vital contracts and water deliveries. In addition, climate change could impact both supplies and demands in the Coachella Valley. Since the DWA shares its groundwater and imported water sources with the CVWD, the supply issues described for that agency, also generally apply for the DWA. These similarities also apply for emerging issues, such as subsidence and invasive species. See CVWD discussion (above).

DWA's annual projected municipal water use is projected to increase from approximately 46,000 AF at present, to roughly 65,000 AF in 2035. Outdoor water use accounts for an estimated 60-80% of the residential and commercial water use within the DWA's Service Area. From 1999 to 2008, DWA reports it added new connections at a rate of about 0.4% per year and peaked at a rate of 3.10% per year around 2008. Average water consumption per active service connection in 2008 was approximately 1,600 gallons per day (0.0048 AF per day).

In summary, DWA finds in its 2010 UWMP that demand will exceed supply during normal, single-dry and multiple-dry years due to the reduction in SWP deliveries as described in DWR's Reliability Report, unless DWA continues to extract groundwater in storage. However, without consistently importing water to offset overdraft in the Whitewater River Subbasin, significant reduction of groundwater in storage will occur. DWA needs to receive greater than 60% of its SWP Table A allocations in order to ensure that demand does not exceed supply in the Upper Whitewater River Subbasin over the next 25 years.

Table 4.19-AZ: DWA Water Supply and Demand Summary

c. DWA Subagency: Mission Springs Water District

Formerly known as the Desert Hot Springs County Water District, the Mission Springs Water District (MSWD) was established in 1953 in the northwestern portion of the Upper Coachella Valley. MSWD provides retail domestic potable water service, as well as wastewater services that include sanitary sewer collection and treatment. MSWD also performs groundwater management. LAFCO notes that MSWD is included in Desert Water Agency's taxing jurisdiction boundary to qualify for SWP entitlements and also receives SWP water from DWA (indirectly via groundwater recharge). Information used in this subsection is from MSWD's 2010 UWMP, unless noted otherwise.

As shown in Figure 4.19.27, MSWD's service area consists of 135 square miles, including the City of Desert Hot Springs, portions of the City of Palm Springs, plus ten smaller adjacent unincorporated communities in eastern Riverside County. MSWD currently provides water service to approximately 36,000 people and sanitary sewer service to approximately 8,000. MSWD water supply and distribution system includes three separate and distinct water supply and distribution systems with the largest of the three systems serving the community of Desert Hot Springs and surrounding communities of West Garnet, as well as North Palm Springs. The two smaller systems, Palm Springs Crest and West Palm Springs Village, are located west of Desert Hot Springs, north of I-10 and abutting the Morongo Indian Reservation.

MSWD's drinking water comes entirely from local groundwater via 14 active production wells, plus additional production from CVWD wells in the Mission Creek Subbasin. CVWD is also contracted with MSWD as an emergency source of water. A third source of water is obtained through an agreement between DWA and MWD which exchange water from the SWP for Colorado River water. DWA then uses this water to recharge the Coachella Basin, the groundwater source used by MSWD and CVWD. Continued recharge will largely be dependent on the future availability of water from the CRA and MWD's exchange agreement with DWA.

MSWD, DWA and CVWD now jointly manage the Mission Creek Subbasin under the terms of the 2004 Mission Creek Settlement Agreement and are collaborating on a water management plan for the subbasin. This agreement and the 2003 Mission Creek Groundwater Replenishment Agreement between CVWD and DWA specify that available SWP water will be allocated between the Mission Creek and Whitewater River subbasins in proportion to the amount of water produced or diverted from each subbasin during the preceding year. In 2009, production from the Mission Creek Subbasin was about 7% of the combined production from these two subbasins.

MSWD also currently operates two wastewater treatment plants: The Horton Treatment Plant and the Desert Crest Treatment Plant have capacities of 2.3 mgd (2,800 AFY) and 0.18 mgd (202 AFY), respectively. The effluent from these plants undergoes a secondary treatment process and is then used for irrigation, wash down at treatment plants or put in percolation ponds near the Mission Creek Fault. MSWD has plans to develop a recycled water system to reclaim and reuse almost all of the wastewater generated within the district for use in landscape and golf course irrigation.

With the development of a recycled water system within the next decade, recycled water could supply a number of landscape and irrigation users that are currently dependent on potable water, thus reducing the demand on groundwater pumping. MSWD currently percolates treated effluent into the groundwater basin. Though this does not reduce the demand for pumped groundwater, it does provide recharge that benefits basin as a whole and lessens the impact of pumping.

With these treatment plants and groundwater recharge programs in place, in 2035, for both dry and multiple dry years, MSWD estimates that it will have a total supply of 44,500 AF and total demand of 22,600 AF, resulting in a surplus of 21,900 AF. The numbers are even better for normal years. Therefore, MSWD has calculated based on

the above that it will be able to meet all of its demands even under the highest future growth estimates and for the driest potential type of hydrology.

MSWD's only direct source of urban potable water is local groundwater. With regional management of the groundwater basin, overdraft of the basin is expected to be managed satisfactorily and water supply reliability is expected to be good. There are reliability concerns, however, with supplies of SWP water used for groundwater replenishment. Projects are under development by regional agencies to ensure the reliability of these supplies.

3. Palo Verde Irrigation District

PVID was organized in 1923 by state legislation, consolidating three water agencies with the main purpose of protecting and conserving water of the Colorado River and the rights to its waters. The irrigation district diverts its water from the Colorado River on the basis of rights dating back to 1877. PVID only supplies irrigation water. It does not provide potable water and does not serve municipal or retail customers. The principal city in the area is Blythe, which with its urban fringe has a population of about 21,800, although more than 8,000 of these are inmates in two State of California prisons. Blythe serves a population of about 30,000 people, some of whom live in Arizona.

a. Notes on PVID

The PVID is located on the west side of the Colorado River in the vicinity of Blythe, California and occupies about 190 square miles of territory in Riverside and Imperial Counties. The District encompasses approximately 131,300 acres, including roughly 27,000 acres on the Palo Verde Mesa, which rises 80 to 130 feet above the valley to the west. Colorado River water supplied through PVID canals is lifted onto the mesa by private pumps to irrigate PVID acreage. The remainder is irrigated from private deep wells.

As shown in Figures 4.19.2 and 4.19.26, the Colorado River forms the eastern and southern boundaries of Palo Verde Valley. The valley is relatively level, approximately 9 miles wide and 30 miles long, and ranging in elevation from 290 feet at the northern end to 220 feet at the southern end. The soils are alluvial from historic Colorado River floods and range in texture from fine grain clays to silty loams to light sandy soils, with the predominant soil being a sandy loam. The entire valley is underlain with permeable sand at shallow depths. The adjacent Palo Verde Mesa, formed by flooding of the Colorado River, is divided into the upper and lower terrace. Farming outside the valley is largely limited to the lower terrace, which is a mile wide and roughly 60 feet higher in elevation than the valley. Soils on the mesa are excessively drained to well-drained fine sand, gravelly sand and loam, older alluvial deposits derived from the adjacent mountains.

In 2003, a total of roughly 93,400 acres were cultivated within the PVID service area. On this acreage, the year-round growing season and multi-cropping practices resulted in a net crop yield of nearly 106,600 acres. The predominant crop on the mesa is citrus, while valley crops are principally alfalfa, sudan grass, cotton, wheat, melons and miscellaneous vegetables. In recent years, the annual value of crops produced within the District has ranged from $60 million to $158 million, excluding livestock.

PVID administers water delivery and the agricultural runoff drain system that services the Palo Verde Valley and Mesa (see Figure 4.19.28 (PVID Service Boundaries)). PVID diverts water from the Colorado River at the Palo Verde Diversion dam for irrigation. It also manages 142 miles of open drains that discharge agricultural runoff into the Palo Verde Outfall Drain. The drain discharges into an old channel of the Colorado River at the Cibola National Wildlife Refuge (in La Paz, Arizona) before joining the present Colorado River channel. The Palo Verde Lagoon and Outfall Drain are listed on the 2010 Clean Water Act Section 303(d) list due to excessive levels of

pathogens and DDT (dichlorodiphenyl trichloroethane). See Section 4.19.2.C ("Water Quality Within the Hydrological Regions") for additional information.

The Palo Verde Diversion Dam was constructed to ensure adequate diversion of irrigation water to farmlands within PVID's service area by maintaining a constant water surface elevation at the canal intake during periods of normal river flow. The diversion facilities were designed to discharge 1,800 cfs into the Palo Verde desilting basin when the river is at the established forebay elevation (283 feet). The dam, spillway and canal headworks were built by the U.S. Bureau of Reclamation. The canals serving the irrigation district were constructed by private interests. The region's groundwater is hydraulically connected to the Colorado River. The groundwater in the valley lies at an average depth of approximately 10 feet, as shown by over 200 observation wells throughout the region. In 1957, the average depth to groundwater was approximately 5.5 feet.

To deliver irrigation water, PVID operates 56 miles of lined canals. To improve distribution, many farm ditches have been concrete-lined in recent years. There are now approximately 315 miles of concrete-lined farm ditches in the valley, about 72% of all private ditches. To drain water back into the Colorado River, PVID operates a drainage system of approximately 140 miles of open drainage channels and 250 siphons (submerged culverts) to carry groundwater drainage and canal operational spill water away from farmland and back to the river. The canal system's main and lateral line capacities range from 2,100 cfs at the upper (northern) end of the district, down to 25 cfs at the various small laterals throughout the valley. In total, the canal system encompasses more than 2,550 structures necessary to operate the system, including canal headings, checks, siphons, deliveries, bridges, flumes, pump plants, moss racks, etc.

b. PVID Water Supply

An abundant supply of water for irrigation has been available for the Palo Verde Valley since the construction of Hoover Dam and the subsequent control of the Colorado River. Due to irrigation practices, the original saline condition of the valley soils, the flat slope of the valley and other related factors, diversion per acre is high. However, considerable water, both operational spill and drainage flow, is returned to the river at the lower end of the valley. Between 1993 and 2002, the average diversion per cropped-acre was approximately 10.28 AF, with an average return flow of 5.21 AF, resulting in an overall net water use of 5.08 AF per net cropped-acre. Operation of a fallowing program in the second half of 2003 resulted in the fallowing of 17,100 acres, with the water saved going to the CVWD.

Irrigation water is delivered to the Palo Verde Valley user for a flat charge of $52.00 per acre per year. This charge, plus the average irrigation district assessment, results in a current total annual water cost of about $61.00 per acre. PVID receives no funding from state or federal governments. PVID operates a land fallowing program in coordination with MWD that pays farmers to fallow their land in lieu of planting a crop that would otherwise lose water to evapotranspiration processes. The 35-year program began in 2004 and is designed to annually set aside a portion of their land, rotate their crops and transfer saved water to urban Southern California. The program complements existing and proposed water transfers with neighboring IID and is the largest and longest water transfer of its kind in California history, providing up to 3.63 million-AF of water over the term of the program. PVID also participated in a short-term emergency fallowing program during 2009-2010 that increase incentives for fallowing land due to severe water shortages in Southern California.

4. City of Blythe

Located on the western bank of the Colorado River, the City of Blythe is the easternmost municipality in Riverside County. It occupies nearly 27 square miles (13,500 acres). Though Blythe is an incorporated munici-

pality, outside Riverside County's jurisdiction and the scope of this EIR, it is included here as a source of information for water resources potentially affected by future development in the surrounding unincorporated Riverside County areas proposed under GPA No. 960 (changes in the area around Blythe Airport, in particular). As such, the information here comes from the City of Blythe's 2005 Urban Water Management Plan ('UWMP,' for this subsection), the most recent document available for the area.

The City of Blythe is geographically isolated, has no water system connections to other areas and has no opportunity for water transfers, wheeling or other exchanges. The local groundwater basin (continuously recharged by the Colorado River) and the Colorado River itself are the only source of water to the area; there are no water imports or supplemental water service (UWMP, page 18). According to Table 4 of its UWMP, Blythe pumped roughly 5,000 AF in 2005 and projects demands of 11,500 AFY for 2010 through 2020, with demand reaching 13,000 AF by 2025.

Blythe's UWMP (page 2) forecasts "reliable water supplies and demands for the city to 2040" as the city uses a groundwater basin with "an (essentially) infinite perennial yield" (UWMP, page 4). For this reason, the city's UWMP concludes that its groundwater supply will "greatly exceed City demand at any point in the future" (UWMP, page 7), even with a projected growth rate of between 3.2% (actual) and 4.1% (projected) per year.

The city's water meets all primary drinking water quality standards, but exceeds several secondary standards (UWMP, page 6). Specifically, the groundwater tends to be high in manganese. Iron levels, color and turbidity are also sometimes exceeded. The municipal system includes secondary treatment for iron and manganese to improve water quality for these constituents. Where private wells are used to supply water, i.e., outside the city, these levels may continue to be exceeded.

For wastewater, all flows from the city (excluding stormwater runoff) are collected and treated at Blythe's wastewater treatment plant (WWTP). The WWTP treats an average of 1.2 mgd (maximum 2.4 mgd) to a secondary level with denitrification. The treatment plant was designed to "expand incrementally" as needed to allow for capacity increases as inflow increases. At build out (projected at 2040), the plant has a planned maximum daily volume of 9 mgd (UWMP, page 25). The WWTP discharges treated wastewater to percolation ponds, where it returns to the groundwater on the downslope groundwater gradient, southeast of the city. All of the city's potable water supply is pumped from the upslope groundwater gradient, northwest of the city.

H. Water Providers in the San Gorgonio Pass and Central Mountains of Riverside County

As noted previously, a variety of water providers serve the San Gorgonio Pass region, as well as the central San Jacinto Mountains area of Riverside County. Of these providers, two are State Water Contractors: the San Gorgonio Pass Water Agency (SGPWA) and the San Bernardino Valley Municipal Water District (SBVMWD), each of which imports SWP water and provides only wholesale water; neither serves any retail customers.

As shown in Figure 4.19.29 (SGPWA Service Boundaries) and Figure 4.19.30 (Groundwater Basins in the SGP Region), SGPWA serves the following retailers: Beaumont-Cherry Valley Water District, Yucaipa Water District and Cabazon County Water District, as well as the City of Banning (which, in turn, serves High Valleys Water District). All of these retail water districts, except High Valleys, also use local groundwater. SBVMWD serves the Yucaipa Valley Water District (YVWD) in the pass, as well as West Valley Water District and City of Riverside in western Riverside County.

Though located primarily in San Bernardino County, both SBVMWD and YVWD also serve portions of unincorporated Riverside County near the border and access groundwater from a basin shared by the area's local Riverside County providers. These water providers are discussed under western Riverside County, above. As with the providers in western Riverside County, in the previous section, the eastern Riverside County providers are detailed here, with expanded details provided for CVWD, in particular, as the region's major wholesaler.

1. San Gorgonio Pass Water Agency

As described in its 2010 Urban Water Management Plan ('UWMP' for this subsection), the San Gorgonio Pass Water Agency (SGPWA) was established in 1961 by act of state legislature. Its boundaries encompass portions of both Riverside and San Bernardino Counties, including the cities of Calimesa, Beaumont and Banning, as well as other unincorporated areas such as Cherry Valley, Cabazon, Poppet Flat and Banning Bench. See Figure 4.19.29.

The SGPWA is one of 29 State Water Contractors responsible for the importation of water from Northern California through the SWP into the contractor's service area. As a State Water Contractor, SGPWA purchases water from the State of California and sells it to the local retail water agencies within its service area. The agency does not provide any direct retail water services to customers.

SGPWA's service area roughly includes: the Yucaipa Valley Water District (17,400 acres), South Mesa Water Company (1,000 acres), Beaumont-Cherry Valley Water District (19,700 acres), City of Banning Water Department (19,600 acres), Cabazon Water District (8,000 acres), Banning Heights Mutual Water Company (900 acres), High Valley Water District (5,300 acres), Morongo tribal lands (34,600 acres) and other unincorporated portions of Riverside County (34,000 acres) and San Bernardino County (1,900 acres). In total, the service area covers 225 square miles, roughly 142,400 acres. See Figures 4.19.1 and 4.19.29. From 2010 to 2035, SGPWA's population is expected to grow from 91,800 to 212,400 residents; an addition of 120,600 people. This is an average annual increase of 3.4%.

a. Notes on SGPWA

SGPWA is only an importer of SWP water; it sells water to local agencies to supplement their supplies and reduce groundwater overdraft. Water supplies available in the SGPWA service area include groundwater, surface runoff and stormwater, recycled water and imported water. Each of these categories of water has unique characteristics that affect long-term yield, seasonality, sensitivity to climatic variation and reliability.

Local sources of water supply in the San Gorgonio Pass area, including groundwater, surface runoff and recycled water have been sufficient to sustain 100% of current water demands. As of 2010, SGPWA had total local supplies of over 33,200 AFY. However, as of 2035, with implementation of planned water recycling, runoff capture and other programs, SGPWA estimates that it will have local supplies of 43,900 AFY. Currently, local supplies are sufficient to meet 90% of water demand, largely due to the declared temporary surplus in the Beaumont groundwater basin. However, by 2013 imported water will become more and more necessary, and will be needed to meet over 30% of annual water demands.

Groundwater sources of supply are numerous and diverse throughout the SGPWA service area, and groundwater pumping occurs in the Beaumont, Banning, Yucaipa and Cabazon groundwater basins. Pumping in Banning and Edgar canyons is also a major source of groundwater. Less the water from Cabazon basin, which is used by water purveyors that do not purchase water from SGPWA, the total groundwater safe yield available from these basins in the SGPWA Service Area totals 17,650 AFY.

GROUNDWATER BASINS IN THE SAN GORGONIO PASS

This page intentionally left blank.

Surface runoff flowing out of canyons in the San Bernardino Mountains within the San Gorgonio Pass area is discharged either westward to San Timoteo Creek or eastward to the Whitewater River. Historical diversions of the Whitewater River to recharge the Banning Canyon groundwater basin within the alluvial bottom of the San Gorgonio River were a component of Banning's water supply. These diversions are no longer performed and the City of Banning has no plans to capture additional surface runoff for groundwater recharge. In the San Timoteo watershed, YVWD captures a long-term average of 1,000 AFY from canyon runoff in Oak Glen and Wildwood Canyons. In recent years, this source of runoff has declined. YVWD is planning to continue capturing runoff for groundwater recharge in the Yucaipa groundwater basin, but is not expecting any additional yield.

Future sources of surface runoff include Edgar Canyon and Noble Creek, which are sources of water that BCVWD is planning to use to provide additional recharge of the Beaumont groundwater basin, in excess of current recharge in channel bottoms. BCVWD has projected long-term annual average runoff in Little San Gorgonio and Noble creeks of 2,000 AFY and 1,000 AFY, respectively. Surface runoff sources from small mountain canyons are highly variable, but BCVWD also plans to capture surface runoff from the San Timoteo gauge at the BCVWD Recharge and Recycle Facility, which can store up to 130 AF and could potentially recharge 9,500 AF.

The use of recycled water to offset potable water demands and for groundwater replenishment is a major component in the supply plans for most of the retail member agencies in the SGPWA service area. BCVWD has installed a large conveyance system for recycled water to be used for landscape irrigation throughout the City of Beaumont. This system is intended to convey 100% of recycled water from the City of Beaumont to specific landscape irrigation customers. Recycled water would be provided to users at approximately 4,500 AFY by 2015, increasing to approximately 9,000 AFY by 2035. At these planned rates of recycled water use, the percentage of total water demand served with recycled sources will be 25% by 2015 and 32% by 2035. This level of recycled water use is comparable to some of the most aggressive water recyclers in Southern California. BCVWD also plans to recharge the Beaumont groundwater basin with recycled water from City of Beaumont and potentially YVWD.

Water recycling is also an important component of the long-term water supply for YVWD. The Henry N. Wochholz Regional Water Recycling Facility produces approximately 3 mgd of advanced tertiary treatment of wastewater from YVWD sewer system, currently discharged to San Timoteo Creek. The treatment capacity of this facility would allow for up to 6.7 mgd, but may be re-rated to 8 mgd. YVWD plans to implement aggressive recycled water use for new development in the City of Calimesa, requiring dual plumbing for front yard irrigation on single-family residential properties.

Similarly, the use of recycled water is a major part of Banning's long-term water supply planning. Banning has plans to upgrade its wastewater treatment plant to meet Title 22 requirements. The first phase of the planned recycled water system will provide water for irrigation at the Sun Lakes Country Club and Golf Course. Also, Banning plans to use recycled water to recharge the West Banning Storage Unit. Part of this project includes the addition of new wells in the vicinity of the proposed recharge location to recover the recycled water. SGPWA operates the Little San Gorgonio Creek Recharge Facility on Orchard Street in Cherry Valley. The facility includes six ponds in which SWP water sent to percolate into the Beaumont groundwater basin for recharge.

By 2035, SGPWA will need more than 25,000 AFY in imported water to meet needs, including mitigating overdraft in the Beaumont Basin. SGPWA is one of 29 water agencies contracted to pay a portion of the SWP debt service. SGPWA's Table A water allocation of the SWP is 17,300 AFY, but Table A is a tool used by DWR to allocate fixed and variable SWP costs and yearly water entitlements to the contractors, it does not reflect actual deliveries a contractor should expect to receive.

While SGPWA has been a SWP contractor since 1962, the ability to use water imported from Northern California is only a recent development. The first phase of the SWP East Branch Extension pipeline was completed in 2003 to convey water to San Bernardino Valley Water District (SBVMWD) and SGPWA. Since 2003, SGPWA has purchased a portion of its Table A allocation to sell to retailers within its service area, including BCVWD and the City of Banning. In addition, SGPWA has reserved a portion of Table A purchases for mitigating overdraft in the Beaumont groundwater basin. Based on DWR's modeling, SGPWA has calculated that for 80% of the years it will have at least 8,000 AFY of SWP water available.

SGPWA also participates in and has studied the feasibility of additional water transfers and exchanges to augment its water supplies. It is a signatory to the Yuba Dry-Year Water Transfer Program from which it receives between 300 and 600 AFY. SGPWA has also participated in water transfers with SBVMWD and the Crestline-Lake Arrowhead Water Agency.

b. SGPWA Water Demands

BCVWD, YVWD, SMWC, CWD and the City of Banning are the five retail water agencies responsible for serving most water demands in the San Gorgonio Pass region and potential imported water demand on SGPWA. Current demands for non-potable water are minimal, but expected to increase to up to nearly 8,900 AFY for BCVWD; 2,800 AFY for Banning; 2,200 AFY for YVWD and over 200 AFY for SMWC; for a total non-potable demand of 14,100 AFY. Each retail water agency has plans for delivering recycled water to serve these non-potable demands.

Between its local supplies, conservation savings and imported water, SGPWA calculates that, for the year 2035 under normal, dry or multiple dry year conditions, it will have 77,800 AFY of total demand and 77,800 AFY in total supply, and therefore in that year and in intervening years, it has sufficient existing or planned supplies to enable it to meet projected demands.

The Morongo Tribe does not currently need imported water and SGPWA does not anticipate that the tribe will need such water in the future. However, if the Morongo Tribe later determines that it will need imported water supplies from SGPWA, the additional demand will be reflected in updates to the SGPWA UWMP. Future water demands included here are derived entirely from data provided by each retail water agency in recent coordination activities, most recent available UWMPs or from information provided to the San Timoteo Watershed Management Authority.

Table 4.19-BA: SGPWA Average Year Water Supply and Demand Estimates

Demand and Supply (AFY)	2010	2015	2020	2025	2030	2035
Total Potable Demands	29,700	31,700	38,800	48,800	58,800	63,700
Total Non-Potable Demands	100	7,600	9,000	10,900	12,900	14,100
Consumptive Demand Subtotal	***29,800***	***39,300***	***47,900***	***59,700***	***71,700***	***77,800***
Minus Other Sources of Supply						
Conservation BMP Reductions	- 0	- 900	- 3,000	- 4,100	- 5,200	- 5,900
Local Supplies from Retail Agencies	-33,220	- 30,400	- 35,500	- 39,100	- 42,700	- 43,900
Total Demand on SGPWA*	**0**	**7,900**	**9,300**	**16,400**	**23,700**	**28,000**

* Totals may not sum exactly due to rounding values to nearest hundred.
Source: SGPWA 2010 UWMP, Table 2-3, pages 2-4.

c. SGPWA Water Availability

Based on the implementation of the identified DMMs, the development of recycled and other water resources projects and the other future actions identified above, in conjunction with existing water supplies, projected

available water supplies would be sufficient to meet projected water demands in normal, single dry and multiple dry years in the year 2035 and the interim.

Table 4.19-BB: SGPWA Water Supply and Demand Summary

Type of Demand or Supply (AFY)	2010	2015	2020	2025	2030	2035
Average Hydrologic Year						
Total Local Potable Water [1]	35,300	24,400	28,300	30,300	31,000	31,200
Total Local Non-Potable Water [1]	100	6,800	8,700	10,400	13,200	14,200
Conservation Savings	--	900	3,000	4,100	5,200	5,900

d. SGPWA Subagencies

Beaumont-Cherry Valley Water District: The Beaumont-Cherry Valley Water District (BCVWD) has evolved from a small privately-owned company that was started to support development in the water districts service area to a system that serves over 35,000 people. The district's current service area covers approximately ten square miles, virtually all of which is in Riverside County and includes the City of Beaumont and the community of Cherry Valley. The water district relies on wells, captured surface runoff, groundwater recharge and reservoir storage to ensure adequate water supply for its residential, commercial and industrial customers.

The service area ranges in elevation from 2,600 feet above sea level in Cherry Valley to over 4,000 feet in the upper reaches of BCVWD's sphere of influence. According to the district's 2005 UWMP, the service area currently provides water to approximately 9,700 service connections. From 2003 to 2005, the district averaged

1600 connections per year – this rate is expected to increase over time. The district is projecting that, by 2015, they will provide water to approximately 32,035 connections within their sphere of interest and approximately 36,070 customers by 2030.

Yucaipa Valley Water District: This water district receives water from both the SGPWA and SBVMWD. As such, YVMWD is addressed under the SBVMWD in the section on western Riverside County water districts. The YVWD, along with BCVWD, the City of Beaumont and the South Mesa Water Company, are members of the San Timoteo Watershed Management Authority (STWA) which engages in watershed planning activities in order to ensure new water sources for the region are developed and used responsibly. STWA does not, however, encompass the entire Pass area. It also disagrees with several of SGPWA's reports and findings relating to various water estimates for the region. For more background on the disputes between the SGPWA and STWA, see the Riverside LAFCO Water and Wastewater Municipal Service Review for the Pass/Mountain Areas (Dudek and Associates, 2005).

2. Water Districts in the San Jacinto Mountains

The San Jacinto Mountains are the largest mountain range in Riverside County and generally separate the western third of Riverside County from the eastern desertous two-thirds that lie between the mountains and the Colorado River on the Arizona border. The region's mountains include parts of the San Bernardino National Forest and Riverside County's highest peak, 10,800-foot Mount San Jacinto, lies six miles north of Idyllwild. The lowest portion of the study area, near Saunder's Meadow, lies as 5,300 feet. While predominantly home to resort communities, the mountains also feature an increasing number of year-round residents, particularly clustered around Idyllwild.

As shown in Figure 4.19.31 (Mountain Water Districts Service Boundaries), the region's domestic (drinking) water service is provided by either the three independent water districts or through private wells (outside the districts' service areas). The three districts, Idyllwild Water District, Pine Cove [County] Water District and Fern Valley Water District have banded together to form the San Jacinto Mountains Area Water Study Agency (SJMA-WSA). This agency has arranged for water studies and serves to coordinate efforts amongst the three water districts in serving the population of the San Jacinto Mountains. (For the purposes of this subsection, the service areas' of the three districts are collectively referred to as the 'San Jacinto Mountain area' or 'mountains' herein.) As none of the three area water districts are required to prepare an urban water management plan, unless noted otherwise, the information provided in this subsection is from the Water Resources Management Plan (WRMP) prepared by Albert A. Webb Associates for the SJMA-WSA, dated May 11, 2005.

a. Background on Mountain Water Districts

Pine Cove Water District: The Pine Cove Water District (PCWD) was established in 1956 as a county water district under the provisions of CWC Section 30000. All water delivered to PCWD customers is produced from its 20 groundwater wells and three jointly-owned (with IWD) wells in Dutch Flats. Unlike the other two districts, PCWD does not currently have any rights to surface water in the area. All of its water supplies come from groundwater sources.

As part of PCWD's corrosion control plan, groundwater from its wells is pumped through the district's aeration facility to remove approximately 80% of the carbon dioxide from the production water and raise the pH level from 6.2 to 7.4 (i.e., lower the acidity of the water).

Idyllwild Water District: The Idyllwild Water District (IWD) was established as a county water district in 1955. IWD relies on a groundwater system as its primary water source. All water produced by IWD is pumped from 23 groundwater wells located throughout the area. IWD also owns a surface water reservoir known as Foster Lake, located on the Lilly Creek watershed. Under state license, IWD is permitted to store 40 AF of water from Lilly Creek each year. The license does not prohibit IWD from storing additional water in Foster Lake, therefore IWD also diverts surface water from Strawberry Creek under a pre-1914 appropriative right. The water stored in Foster Lake is used to recharge the groundwater used by IWD through infiltration. Once the lake is fully filled, the excess water flows downstream via Strawberry Creek. According to the WRMP (page 8), during a normal year IWD diverts an average of 119 AFY from Strawberry Creek. During the drought years of 1999 - 2002, the district diverted an average of 47 AFY (though only 0.34 AF in 2002).

IWD also owns and operates the only public wastewater collection system in the mountain communities. This system serves the central part of the IWD service area, roughly 600 connections (including 2% of FVWD's users), encompassing Idyllwild's commercial district, restaurants, motels and Idyllwild School (WRWP, page 2). All others use individual septic systems. The collected wastewater is treated at IWD's 0.25-mgd (million gallons per day) extended aeration treatment facility. Treated effluent is then conveyed by gravity to a system of percolation ponds and hillside irrigation for disposal. The average flow through IWD's treatment plant is approximately 100,000 gallons per day (gpd) and the average annual total treated is roughly 116 AFY (WRWP, page 9).

Fern Valley Water District: The Fern Valley Water District (FVWD) was established as a county water district in 1958. FVWD derives nearly 82% (135 AFY) of its total water production (165 AFY) from surface water supplied by Strawberry and Tahquitz creeks. During a normal water-year, surface diversions averaged 48 AFY and 74 AFY from Strawberry Creek and Tahquitz Creek, respectively. However, FVWD diverts less than its full licensed amount due to limitations on its current infrastructure for intake and storage. During the last extended drought, between 1999 and 2003, FVWD only diverted an average of 16 AFY and 73 AFY, respectively, from the two creeks.

FVWD's supply system consists of a surface water filtration plant and 14 active wells. When surface water is available, the district operates the filtration plant to treat water diverted from the aforementioned creeks. Once filtered, the water is provided to FVWD customers by gravity feed. The filtered surface water is augmented by water produced from wells on an as-needed basis (e.g., during dry month periods of peak demand). Per the WRMP (page 8), FVWD is also not diverting their entire licensed water allotment. This is reportedly because flow at the diversion structure "often falls below" the source's intake point and the district only has a storage capacity of 22.25 AF.

b. Mountain Area Water Supply and Demand

Because of their location on "the Hill," none of the three water districts are members of the SWP or otherwise affiliated with a State Water Contractor nor do they receive any SWP water or other imported water. PCWD's water supply comes solely from local groundwater sources. The other two districts utilize a combination of groundwater and surface water supplies from local streams and springs (though only FVWD diverts directly from surface waters). As such, these water supplies are dependent on the amount of precipitation (rain and snow) that falls locally in the watershed. Groundwater recharge in the area occurs through infiltration and percolation of precipitation, surface runoff in stream channels and percolation of delivered water (returning to the groundwater's fractured rock aquifers after use in irrigation, septic systems, etc.).

As the amount of precipitation occurring in any given year can vary unpredictably, available water supplies are characterized in two ways: normal precipitation periods and critical dry periods. For the region, 'normal

precipitation' is defined as a minimum of 28 inches per year, while a 'critical dry period' (CDP) is defined as having 16 inches or less precipitation per year. The drought between 1999 and 2003 was a CDP.

During an NPP, the San Jacinto Mountains area gets about 2,200 AFY of recharge and a similar amount (2,200 AFY) of total outflows, including approximately 1,700 AFY of subsurface outflow. Average groundwater pumping quantities for the three water districts plus groundwater extracted by private wells during an NPP is approximately 560 AFY. Estimates indicate that groundwater storage is approximately 66,300 AF within the study area during NPPs. See Table 4.19-BC (San Jacinto Mountain Area Water Production and Usage). According to the WRMP (page 7), the results of water budget calculations indicate that during normal precipitation periods (NPPs), based on limited groundwater level data, the groundwater is assumed to be in equilibrium and no change in storage occurs.

Water production values from the WRMP for each of the three districts are provided in Table 4.19-BC, below. The 2005 WRMP concludes: "Based on recorded water production and projected…estimates, NPP supply with current/near future water supply facilities is adequate to meet projected residential and commercial NPP water demands, including unaccounted water and other usage through 2020."

During critical dry periods (CDPs), approximately 1,400 AFY of recharge is calculated to occur. Of this, nearly 570 AFY is extracted from the basin as groundwater. Though basin-wide static water level data was not available for the last CDP (1999 to 2002), the WRMP estimates the mountains have approximately 64,000 AFY of groundwater storage during a CDP. However, it also notes that, "Further studies would need to be performed to determine the amount of water economically recoverable during a drought event." (WRMP, page 7.)

Water supply was also evaluated in the WRMP on both an annual and peak month basis to determine if each district has adequate supply and/or storage capacity to meet peak day demands during the peak summer months of a CDP. During CDPs, the WRMP finds (on page 11) that the three water districts will "likely have enough existing/near future CDP water supply to meet projected annual CDP water demands, including unaccounted water and other water usage by the year 2020," but that currently they cannot meet peak-day demands during CDPs. The study notes that "in order to meet the projected annual [CDP] demands, the districts must achieve annual water demand reductions equal to or greater than those achieved in 2002 through their Water Shortage Emergency Plan or other water conservation measures," that is, a "4% reduction."

Table 4.19-BC: San Jacinto Mountain Area Water Production and Usage

Water District	Average[1] Water Production (AFY)			Average Water Usage (AFY)				Projected Average Water Demand (2020) (AF)
	Groundwater	Surface Water	Total	Resi. & Commerc.	Other Usages[2]	Storage & Unacct.[3]	Total	
PCWD	121.7	NA	**122**	109.3	NA	12.4	**121.7**	**144.1**
IWD	309	137.2 [4]	**308.7**	273.6	9.7	7.3	**290.6**	**294.9**
FVWD	55.7	113.5	**169.2**	134.6	NA	34.6	**169.2**	**204.1**

Key: AFY = acre-feet per year NA = not applicable

Footnotes:

1. Based on roughly 10-year average (1993-2003).
2. Sewer plant, office, fire and water-line flushing uses.
3. Storage, system losses and other unaccounted for water.
4. Net stream diversion. (Note: All water distributed by IWD is pumped from its groundwater wells. However, the district has the right to divert surface waters and to store up to 40 AFY in Foster Lake, IWD's reservoir.)

Mountain Water Districts, as indicated

Figure 4.19.31

SERVICE AREA BOUNDARIES OF MOUNTAIN WATER DISTRICTS

This page intentionally left blank.

In general, water quality within the San Jacinto Mountains tends to be very good, according to the WRMP. The water tends to be very 'soft' due to its sodium and calcium bicarbonate levels. Exceptions, however, occur for Saunders Meadow and Dutch Flats, where IWD records indicate elevated nitrate and iron/manganese levels, respectively. Outside of these areas, occasional 'spikes,' short-term increases, in iron or manganese concentrations were also noted, but are not considered relevant to the supply's overall water quality.

Table 4.19-BD: San Jacinto Mountain Area Water Demand Summary

Water District	Projected Annual Water Demand* (AF)				Projected Demand 2020
	2005	2010	2015	2020	
FVWD	135.6	158.2	173.0	188.3	204.1.1
IWD	253.6	279.9	284.4	289.7	294.9
PCWD	111.1	133.0	136.7	140.4	144.1

*Does not include storage and unaccounted water.

c. Mountain Water Supply Reliability

In the WRMP, projected water demand requirements for each district for 2020 were calculated using recorded unit water demand values, rather than the typical gallons per day. This is necessary because the resort nature of the region means usage rates change seasonally. Seasonal occupancy tends to be highest during the summer months (June through September), with July and August seeing peak water demand. Accordingly, water demand increases over the next decade are expected to be due mainly to conversion of part-time occupancy to full-time residences, growth in tourism activity and a small population increase. Recorded water use data indicates that approximately 60% (330 AF) of the total water used by customers of the three water districts is used outside the home. This is despite the fact that many residents of the mountain communities do not irrigate their properties, depending on the type of landscaping present, and even that irrigation typically is only used between May and September of each year.

Table 4.19-BE: San Jacinto Mountain Area Peak Water Supply and Demand

Water District	CDP Average-Day Supply [1]		Total Supply	CDP [2] Peak-Day Demand	Projected CDP Peak-Day Water Demand			Esti. Supple. Flow [3]	Avail. Stored Supply [4] (days)
	GW	SW		Esti. 2002	2010	2015	2020	2020	2020
PCWD	123	NA	**123**	162	191	196	228	105	16
IWD	235	NA	**235**	314	348	356	362	127	14
FVWD	150	0	**150**	148	199	216	235	85	35

Key: GW = groundwater SW = surface water NA = not applicable
Footnotes:
1. Average-day supply during peak month, in gallons per minute (gpm).
2. CDP = critical dry period (precipitation of 16 inches per year or less).
3. Estimated supplemental flow required from storage or additional supply, in gpm.
4. Days of available water supply from domestic storage.
Source: San Jacinto Mountain Area Water Study Agency, Water Resources Management Plan, 2005, Table E-1, page 11.

As shown in Table 4.19-BE, above, with current water supply facilities, all three districts could experience a water supply shortfall in trying to meet existing and projected peak-day water demand during a critical dry period. The amounts listed under "Estimated Supplemental Flow" in the table would offset the shortfall, but with the potential to drawdown existing groundwater levels, for which the total aquifer capacity is not fully known. To lessen the potential severity of such a shortfall, all three districts have various demand management measures and water conservation programs that could be implemented as part of each district's water shortage emergency plans. The districts also have ongoing conservation programs, incentives (rebates, for example) and educational materials to foster conservation even during non-drought years.

According to the WRMP, groundwater data indicate that the region is not in an overdraft condition during NPPs. For CDPs, there is not sufficient data to determine if the local groundwater becomes overdrafted. However, the WRMP states (on page 13) that it appears that, "Short-term overdraft during critical dry periods would be compensated for during normal precipitation periods. Thus, it is assumed that the [San Jacinto Mountains] study area can sustain the water demands of district and private pumping." That is, any shortages would generally be due to insufficient supply infrastructure (pumping and/or storage), rather than water deficits, *per se*.

For this reason, the WRMP indicates that supplemental water supply (to solve the shortage potential indicated in Table 4.19-BE) could be obtained in the form of groundwater produced by new (additional) wells. The WRMP estimates that in order to meet 2020 demand, the three districts would need to construct additional groundwater wells and would need more than 1.5 million additional gallons of storage capacity to provide an additional seven days of water supply for projected CDP peak-day demand.

In all, the WRMP concludes that water supplies are sufficient to meet normal year demands, including peaks, but that infrastructure improvements (particularly additional wells and storage capacity) are needed to fully ensure adequate peak demand supplies during critical dry periods (i.e., droughts). It also concludes that it appears the area's recharge rates are probably sufficient to adequately replace any short-term groundwater drawdown that would occur during droughts due to increased (but temporary) reliance on groundwater to meet supply shortfalls. As such, sufficient water supplies would be adequate to meet all demand conditions through at least 2020 (and likely further, due to currently slow growth conditions). However, throughout the report, it is stressed that there is a lack of conclusive water basin data necessary to fully verify these assumptions.

I. Areas Not Served By Existing Water Purveyors

A number of water districts within Riverside County serve their customers using only groundwater and/or surface water. These include all of the water districts in the centrally located mountains San Jacinto Mountains in Riverside County: the Pine Cove, Idyllwild and Fern Valley water districts, for which their elevation makes importing water economically impractical at present. At the far eastern edge of Riverside County, the City of Blythe solely uses groundwater and the Palo Verde Irrigation District provides non-potable agricultural water, both derived from the Colorado River. These districts are both fairly isolated geographically and served by the major water source that is the Colorado River. Lastly, several districts in western Riverside County, the Jurupa and Rubidoux Community Service Districts (CSDs), in particular, also rely only on groundwater. The rest of Riverside County's water districts serve their customers with imported water (SWP and/or Colorado River), often-times supplemented with local groundwater. This is particularly true of districts in which the local groundwater basins are in overdraft condition or have water quality issues. These districts are all discussed above.

Beyond the territories served by formal water agencies, where no piped water supplies are available, individual properties or developers must provide their own water. In most cases, this would be from existing groundwater basins, unless unavailable or infeasible (e.g., due to topography, geology, etc.). The proposed project, GPA No. 960, includes a number of land use changes in areas outside of established water districts or other water purveyors (mutual water companies and other private providers). These are discussed here.

1. Service Needs

As outlined in the preceding sections, most of Riverside County's developed regions are served by water agencies providing wholesale and/or retail water supplies to municipal (residential, commercial, etc.) users, industrial/institutional users, agricultural users and others. Such customers receive their water supplies through piped connections to the provider's infrastructure. Even within these water districts, however, some water users

may obtain their water from local sources via private wells or other private ventures. Typically such private wells either predate formation of the area's agency or lie in regions not yet served by agency supply lines. The water agency discussions presented previously, however, take into account the effect of such private wells, as well as any other appropriative water rights, on their district's supplies and future reliability. See discussions above for specific districts.

In regions of Riverside County not served by a public water provider, water supplies are obtained either from private, onsite (self-serving) wells or from connection to a small-scale water provider, either a public or private entity, that obtains and distributes water supplies to its local customers. As an example, a local water company might be formed to provide water to a golf course and surrounding vacation homes or to serve a rural mobile home park where no public water provider is available. Water supplied by such providers typically comes from groundwater basins, usually underlying the area served. Water may also be supplied from surface water by right. However, due to the semi-arid Southern California climate and hydrology, reliance on such sources are not very common. Lastly, a water company may also obtain (import, essentially) water from a public water provider, for example, if the company lies within the agency's service area.

2. Additional Water Demand

Thus, in areas outside of established public water providers, any new development would rely on private (typically onsite) well water. This would be the case for any future development accommodated by GPA No. 960's proposed General Plan changes. Thus for the portions of GPA No. 960 with known spatial components that are located *outside* of a water district or provider, the underlying groundwater basin would be the typical source for water. See Table 4.19-BF (Groundwater Basins Underlying Non-Served Areas, below, for a summary of this data. (See Section 4.19.7.B for a discussion on the methodology used.) The groundwater information presented here addresses the groundwater basins, as defined by the California DWR, expected to serve as the water sources used for such private wells. See Section 4.19.4.B for descriptions of each of these groundwater basins.

In Table 4.19-BF, it should be noted that it includes the areas of proposed changes around the Blythe Municipal Airport in unincorporated Riverside County. This is necessary because these areas have no municipal water supplier; the Palo Verde Irrigation District only provides non-potable agricultural water. When no retail water supplier is available, development must 'self-serve,' meaning pump water directly onsite or arrange for water from a nearby private source. For estimated effects of development on groundwater in the area, see the discussion under "City of Blythe" earlier in this section.

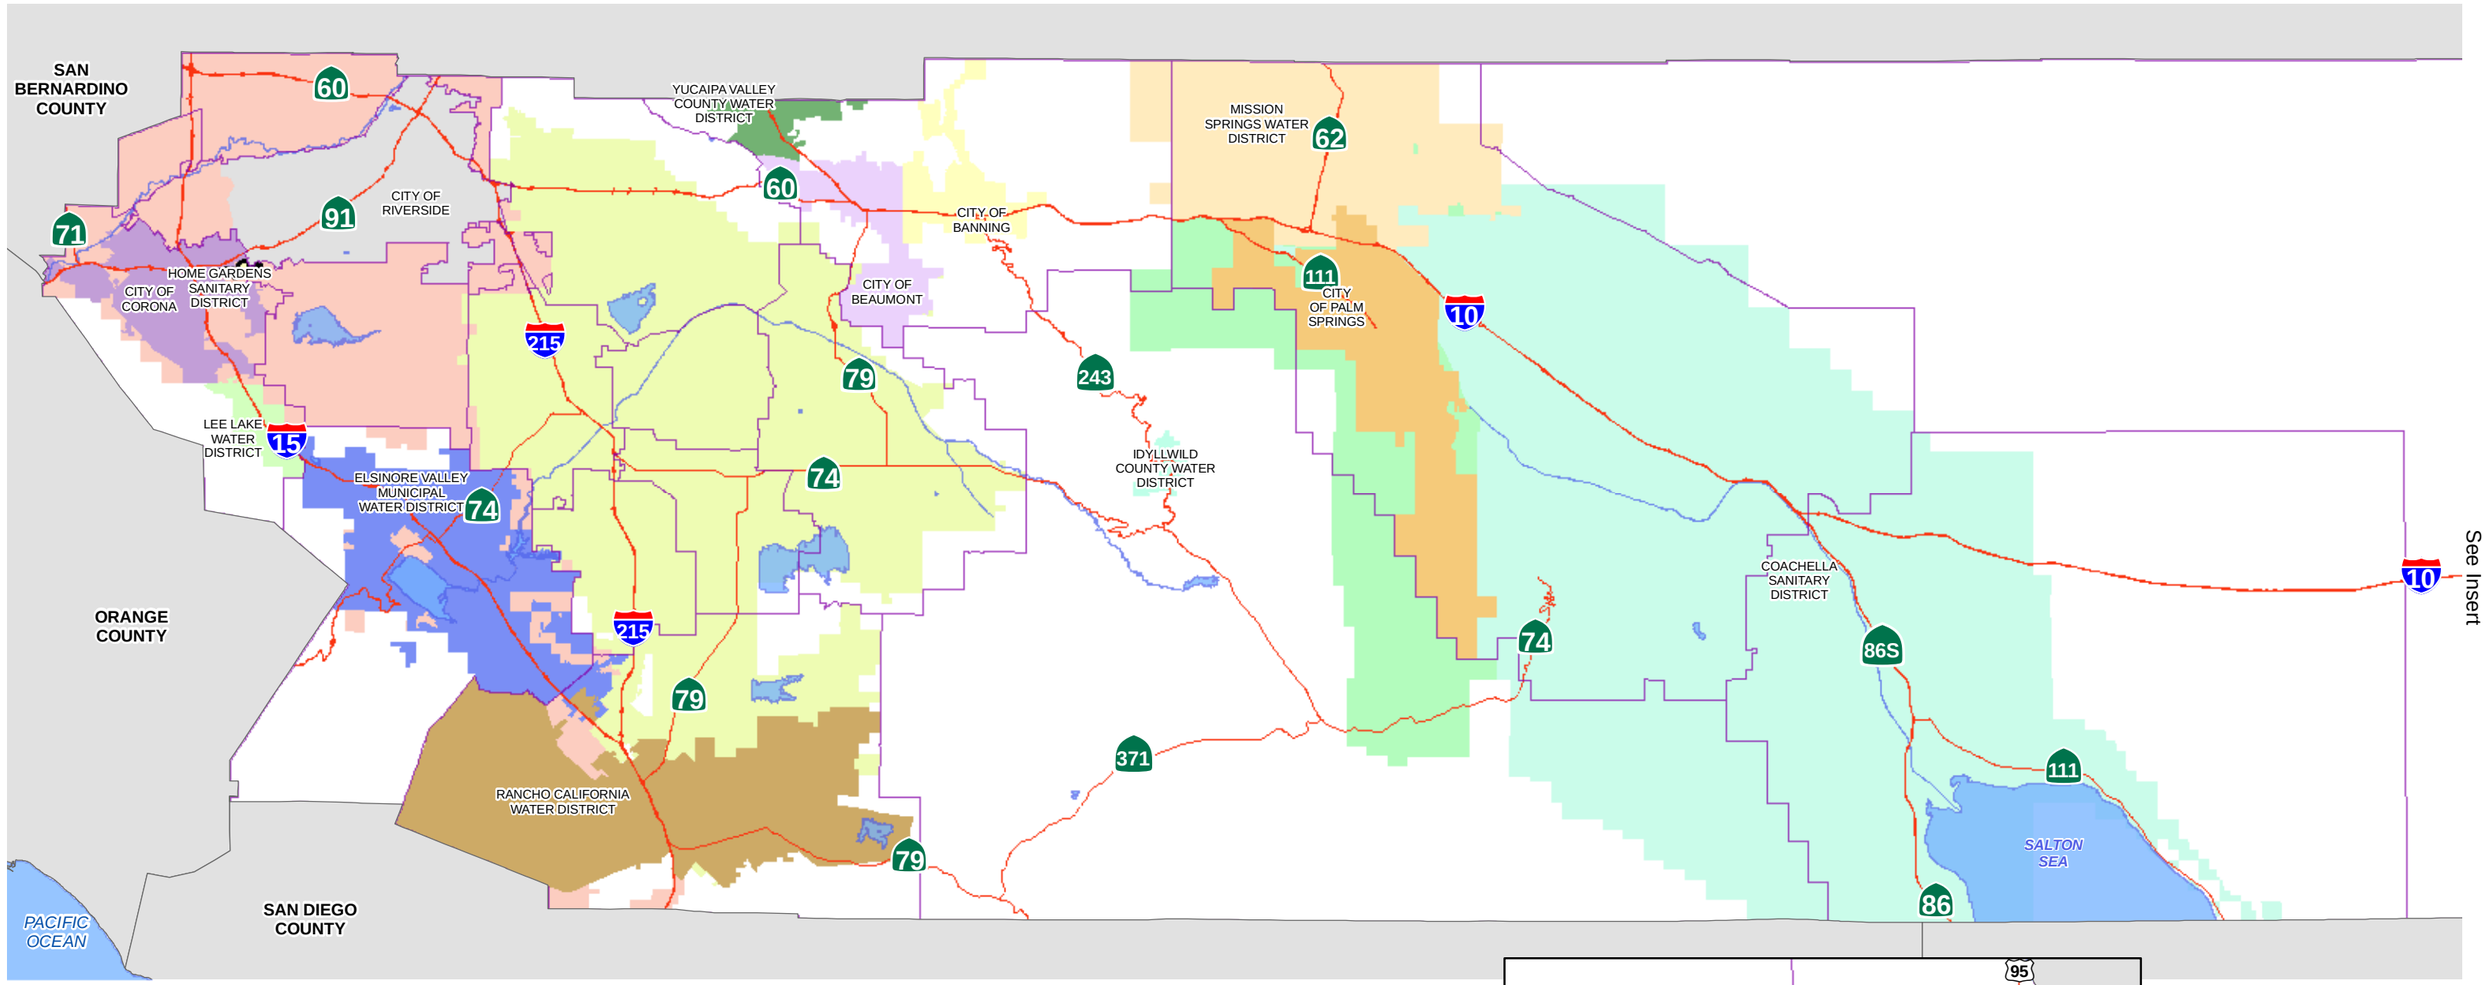
J. Local Sewer and Wastewater Treatment Providers

Sewage is generated anywhere humans live, work or visit. To protect human health, as well as the environment (particularly water quality), sewage must always be collected and treated in some fashion. Most simplistically, sewage may be captured in holding tanks which are later collected and transported for disposal into a municipal (sanitary) sewer system. Examples include port-a-potties, RVs, boats and catering trucks.

All habitable structures in Riverside County are required to provide some form of sanitary facilities (e.g., toilet and washroom) with an appropriate means to safely collect and dispose of the sewage that result. For fixed locations, such as homes, businesses, schools, offices, etc., in most urban and suburban areas sanitary sewer connections convey wastewater to wastewater treatment facilities that are typically operated by public entities (cities, water districts, sewer districts, community service districts, etc.) or, occasionally, as smaller-scale neighborhood or community facilities. Because of its close connection to water supply, many water districts also handle sewer (wastewater) services, its collection and/or treatment, as well. The water that results from wastewater treatment can be reclaimed, recycled or reused, depending on the type of treatment it receives and the water needs of the region, otherwise it is discharged into live streams where it is then used downstream for beneficial uses and eventually flows to the ocean.

A variety of information regarding wastewater is also included under the various local agency descriptions presented in Sections 4.19.4.E through 4.19.4.I. Table 4.19-BG (Sewer and Wastewater Treatment Providers in Riverside County) lists the agencies that provide sanitary sewer collection and/or wastewater treatment. Figure 4.19.32 (Wastewater and Sewer Providers in Riverside County) shows sewer-providing districts. Table 4.19-BH (Wastewater Treatment Facilities in Riverside County) lists the wastewater treatment facilities in Riverside County (regardless of jurisdiction). It should be noted that some agencies only provide sanitary sewer services for portions of their service areas, that is, their sewer service areas may be different than their water service areas. In locations without sanitary sewer connections, septic systems (OWTS, see below) or storage and offsite transport must be used instead. And, in some cases, locations that were on septic systems prior to sanitary sewers being made available may not yet have connected to the sanitary system.



- City of Banning
- City of Beaumont
- City of Blythe
- City of Corona
- City of Palm Springs
- City of Riverside
- Coachella Sanitary District
- Elsinore Valley Municipal Water District

RIVERSIDE COUNTY PLANNING DEPARTMENT

SEWER AND WASTEWATER TREATMENT PROVIDERS IN RIVERSIDE COUNTY

Path: \\agency1\mapjis\Projects\Planning\Cindy\PurpleMapGallery\Fig4.19.32-SewerandWastewater.mxd

This page intentionally left blank.

Generally synonymous with sewage, 'wastewater' includes sewage and all other waste substances associated with human habitation, or of human or animal origin, as well as any from producing, manufacturing or processing operations. This is in contrast to stormwater and urban runoff (discussed under Section 4.19.2.D) which consists of water from precipitation events (rain, snowfall, snowmelt, etc.), irrigation and the like, which can generally be discharged into surface waters with little or no intensive treatment if not polluted. For municipal wastewater treatment facilities, wastewater is treated in up to three levels (processed sequentially) as follows:

Primary: Sewage solids are removed, generally through sedimentation, with no biological oxidation. Primary effluent has only limited reuse allowed for surface irrigation of orchards and some crops.

Secondary: Treatment adds further removal of organic materials through biological processes. Reuse is allowed, including for groundwater recharge and a broader array of irrigation applications. This level is the one typically achieved for most wastewater effluent.

Tertiary: This level adds chemical flocculation (removal of minute solids), sedimentation and filtration. Varying degrees of disinfection are applied through various means. Tertiary-treated water reuse is permitted for some uses involving potential body-contact, including irrigation of golf courses and parks, as well as in recreational lakes.

Onsite Waste Treatment Systems (OWTS): The third type of sewage facility is septic systems (or, more properly, onsite waste treatment systems, OWTS) which are typically built in the ground and serve individual sites or sometimes neighborhoods or small communities. These types of systems serve to split the wastewater into two portions. Solids generally settle out (i.e., into septic tanks) and must eventually be pumped out and disposed of into a sanitary treatment system (WWTF or otherwise). The liquid, on the other hand, is generally allowed to percolate into the surrounding area through leach fields and similar methods. (It is for this reason that septic systems are not permitted in all areas; the soils upon which it is constructed must be capable of percolating water. Solid bedrock, for example, does not.)

The purpose of a septic system is to effectively accept and treat liquid wastes from a residence, commercial or industrial facility, and to prevent biological and nutrient contaminants from polluting water supplies and waterbodies. Most of this treatment happens in the soil below the absorption field. The physical and chemical properties of the soils combine with microscopic organisms to decompose or prevent movement of contaminants.

In soil not saturated with water, biological contaminants (bacteria and viruses) are usually absorbed and rendered inactive within a few feet of the absorption field. Some nutrients, on the other hand, can travel much greater distances, depending on the type of soil, the amount of concentration of waste and the age of the system. Loam and clay soils, for example, have a greater long-term ability to absorb nutrients and prevent them from moving through the soil than do sand and muck soils. In their journey, nutrients or biological contaminants that encounter soil saturated with water can move much greater distances, in some instances, as much as several hundred feet.

If not located, constructed and operated properly, septic tanks can contaminate drinking water sources with pathogens or nutrients. A single failing septic tank system can pose an infection risk and even an immediate health threat if the infectious agent is not controlled by water treatment. The risk from nutrients is related less to individual septic tank systems than to the cumulative effects of many systems. The nutrient load from one septic tank system is unlikely to be significant. On average, a human excretes 4 to 5 kilograms of nitrogen wastes per year, about half of which will be released into the soil. However, adding new systems in an area that already has

high nutrient levels may trigger problems. Nutrients can build up in the soil and groundwater over time to reach unhealthy levels or encourage the growth of algae, making water treatment more expensive.

Table 4.19-BG: Sewer and Wastewater Treatment Providers in Riverside County

Operator	Only Partial Service	Collection	Wastewater Treatment	# (and Type) of WWTFs[1]

Key: WD = Water District CSD = Community Services District CSA = County Service Area ns = not specified

Footnotes:

1. Wastewater Treatment Facility types: sec = secondary, tert = tertiary, adv = advanced. For agencies not providing their own treatment, the agency treating the wastewater (and the facility, if known) is in italics.
2. Per a 1988 agreement, Palm Springs provides primary and secondary treatment; DWA provides tertiary.
3. In addition to WMWD's two wastewater treatment facilities (tert. and sec.), wastewater treatment services are also provided by the City of Riverside, EMWD and RCWD for certain portions of WMWD's service area.
4. A joint powers agency responsible for collecting, treating and reclaiming member agencies' wastewater. Members are City of Norco, Home Gardens Sanitary District, Jurupa CSD, WMWD and Santa Ana Water Project Authority. The WRCRWA plant is located within the JCSD service area and is operated by WMWD.
5. Facility within this agency's service area, but operated by the agency indicated.

4.19.5 Policies and Regulations Addressing Water Resources

Water resources in California are regulated at both the state and federal level. In addition, and as identified throughout this analysis, local laws and regulations in the form of ordinances, resolutions, policies, procedures and other forms of governance also can and do apply to water resources. Key water laws and regulations are discussed below. This information is intended as a brief overview of current regulations for water and wastewater systems, and is intended to provide basic information for those who may be unfamiliar with the complex and detailed regulatory requirements.

Numerous federal, state and local laws and agencies regulate water and wastewater. Some of these state and regional plans and policies also build upon the federal legislation. In other instances, federal acts have established broad goals, which are to be achieved through implementation at the state or local level. Finally, there are some regulations that are unique to California. Oft-times there is considerable, and confusing, overlap among the agencies, regulations and associated acronyms. The following discussion identifies a few of the major federal, state and local regulatory bodies and requirements for water programs.

A. Federal Laws and Regulations

1. Federal Water Pollution Control Act of 1972 (aka the Clean Water Act)

The federal Water Pollution Control Act is more commonly known as the 'Clean Water Act' (CWA). With its amendments, the CWA is the principal law governing the nation's streams, lakes and estuaries. It contains regulatory provisions that impose progressively more stringent requirements on industries and cities to reduce pollution and meet the goal of zero discharge of pollutants. The CWA established as national goals the elimination of pollutant discharges to the navigable waters and the assurance that all navigable waters would be fishable and swimmable. The U.S. Environmental Protection Agency (EPA), which is charged with chief CWA implementation, also established the regulatory standards listed below. Other applicable sections of the CWA are also listed below.

- No one has the right to pollute the navigable waters of the United States. Dischargers are required to obtain permits.
- Permits shall set limits on the concentration of the pollutants being discharged. A violation of the limits carries a penalty of fines or imprisonment.
- The best technology available shall be used to control the discharge of pollutants.

a. CWA Section 303(d) – Impaired Waters List and Total Maximum Daily Loads

This section of the CWA requires each U.S. state to identify waters that do not meet water quality standards after application of technologically based controls. These applicable water quality standards include designated beneficial uses and adopted water quality objectives. Waterways are identified as designated 'water quality-limited segments' and are prioritized for purposes of developing total maximum daily loads (TMDLs) and establishing load and waste load allocations. The TMDL is the sum of waste load allocations for point sources of pollution and load allocations for non-point sources of pollution, plus natural background sources. Essentially the TMDL is the amount of a pollutant that can be discharged into a water body and still maintain water quality standards. The resultant '303(d) list' includes the size of the waterbody, the sampled pollutants affecting designated beneficial

uses, the source of the pollutant and the water body's priority status with regard to developing TMDLs, which serve as limits on discharged pollutants in order to overcome the water quality impairment. Water quality impairment issues affecting Riverside County water bodies are discussed in Section 4.19.2.C.

b. CWA Section 303(c)(2)(B) – National Toxics Rule

In November 1991, the U.S. EPA proposed chemical specific, numeric criteria for priority toxic pollutants, including dioxin and pentachlorophenol, necessary to bring all states into compliance with the requirements of Section 303(c)(2)(B) of the Clean Water Act. The requirement, known as the National Toxics Rule (NTR), established ambient human health criteria for 57 priority toxics, ambient aquatic life criteria for 23 priority pollutants and a compliance schedule.

Implementation of the NTR lagged for several years due to court challenges on the human health criteria for dioxin and pentachlorophenol but is now in effect. In 2000, the California SWRCB adopted a policy for implementation of the NTR that established implementation procedures for three categories of priority pollutant criteria or water quality objectives. These are: (1) criteria promulgated by EPA in the NTR that apply in California; (2) criteria proposed by the EPA in the California Toxics Rule; and, (3) water quality objectives contained in RWQCB water quality control plans (basin plans).

c. CWA Section 319 – Non-Point Source Management Program

Section 319 regulates non-point source pollutants, which enter water from diffuse sources. Non-point source pollutants are often chemicals from lawns, automobile residues or urban runoff that enter the wastewater stream and water supply in large quantities and sudden surges, largely due to storms. Although California adopted a Non-point Source Management Plan (NPSMP) in 1988, cities and counties have only recently begun adopting local implementing rules and regulations. Because of its widespread nature, control of this type of pollution has proven to be difficult and is expected to require costly upgrades to existing facilities and permits, particularly for wastewater facilities with high rates of infiltration.

d. CWA Section 401 – State Water Quality Certification Program

Prior to the issuance of federal CWA permits, the SWRCB, through its nine regional boards, certifies the quality of surface waters pursuant to Section 401 of the CWA. Section 401 requires that activities and facilities that would discharge pollutants into waters of the U.S. must obtain a state water quality certification permit proving that the activity complies with all applicable water quality standards, limitations and restrictions.

e. CWA Section 402 – National Pollutant Discharge Elimination System

In 1972, the CWA was amended to prohibit the discharge of pollutants to waters of the U.S. unless the discharge is in compliance with a National Pollutant Discharge Elimination System (NPDES) permit. The NPDES permit program focuses on point source discharges from municipal wastewater plants, but also applies to industrial discharges, construction site dewatering discharges and stormwater discharges to surface waters. Municipalities, publicly owned treatment works and most industries in the U.S. are now required to obtain an NPDES permit for discharges, including stormwater runoff. NPDES permits regulate discharge of "pollutants from point sources to waters of the United States" to ensure that the discharges do not adversely affect surface water quality or beneficial uses. In addition to CWA Section 402, NPDES permits are authorized by CWC Section 13370 and Chapters 3 and 4 of CCR Title 23. The responsibility for issuing NPDES permits in California has been

delegated to the nine Regional Water Quality Control Boards, subject to review and approval by the Regional Administrator (US EPA Region IX, San Francisco).

f. CWA Section 404 – Permits for Dredged or Fill Materials

CWA Section 404 permits are issued by the U.S. Army Corps of Engineers (ACOE) for the placement of dredged or fill materials (essentially, soil) into waters of the U.S., including wetlands. 'Waters of the U.S.' are navigable waters, tributaries thereto and adjacent wetlands, and other waters where their degradation or destruction could affect interstate of foreign commerce. The CWA Section 404 permitting process is designed to ensure that the chemical, physical and biological functions of the waters are protected. It includes mandatory measures to avoid, minimize and mitigate impacts. Further, by Executive Order, these permits are to ensure "no net loss" of wetlands within the U.S.

2. Safe Drinking Water Act

Drinking water quality is regulated under the authority of the federal Safe Drinking Water Act of 1974 (SDWA) (42 USC Section 300(f) *et seq.*) and associated regulations implementing that statute. The federal act authorizes the U.S. EPA to establish minimum standards to protect tap water from potentially harmful contaminants and requires all owners or operators of public water systems to comply with these primary (health-related) standards. The 1996 amendments to SDWA require that the EPA consider a detailed risk and cost assessment, and best available peer-reviewed science, when developing these standards.

The federal law establishes National Primary Drinking Water Regulations (NPDWRs or primary standards), which are legally enforceable standards that apply to public water systems. Primary standards protect public health by limiting the levels of contaminants in drinking water. National Secondary Drinking Water Regulations (NSDWRs or secondary standards) are non-enforceable guidelines regulating contaminants that may cause cosmetic effects (such as skin or tooth discoloration) or aesthetic effects (such as taste, odor or color) in drinking water.

In 1996, the SDWA was amended to require states to identify potential contamination threats and determine the security of drinking water sources. The amendment also required that qualified professionals operate water systems, although California had already established a certification program. Other requirements include the following:

Consumer Confidence Reports: Since 1999, public water systems must provide their customers with an annual water quality report providing data about the quality of the local drinking water, compliance with EPA's safety standards, sources of any contaminants, and potential health risks. The annual reports are included with water bills for systems with more than 10,000 customers; for smaller systems the information can be posted at a central location or published in local newspapers.

Water Conservation Plans: In 1998, the EPA issued guidelines for water conservation plans for public water systems. Now states may require a water system to submit a water conservation plan consistent with the EPA guidelines as a condition of receiving a loan.

Proposed Arsenic Standard: The EPA established the maximum allowable limit for arsenic in drinking water from 50 parts per billion (ppb) down to 5 ppb. Arsenic can produce a variety of health-related problems, including cancer, cardiovascular disease, neurological damage, and diabetes. Many water supplies in California are

significantly higher than the 5 ppb level and would not meet the proposed standard without additional (and possibly very costly) treatment.

3. Bio-Terrorism Preparedness and Response Act

This act addresses the security of water and wastewater systems. It requires every community water system that serves a population of greater than 3,300 persons to conduct a vulnerability assessment, certify and submit a copy of the assessment to EPA, prepare or revise an emergency response plan that incorporates the results of the vulnerability assessment and certify to EPA, within six months of completing the vulnerability assessment, that the system has completed or updated their emergency response plan. Basic elements of a vulnerability assessment include: a characterization of the water system (i.e., mission and objectives); identification of avoidable adverse consequences; determination of critical assets that might be subject to terrorism; assessment of the probability of acts of terrorism occurring; evaluation of existing countermeasures; and development of a plan for reducing risks.

B. State Laws and Regulations

The California Water Code (CWC) is the principal set of regulations governing water supply and use in the state. The Code controls water rights, the construction and management of dams and reservoirs, flood control, conservation, development and utilization of state water resources, water quality protection and management, plus management of water-oriented agencies. The water quality provisions set forth in the CWC have been written to supplement provisions of the California Health and Safety Code, Public Resources Code, Fish and Game Code, Food and Agriculture Code, Government Code, Harbors and Navigation Code, CEQA and California Endangered Species Act. Other laws within the CWC or other state statute include the following:

1. California Porter-Cologne Water Quality Control Act of 1970

Division 7 (Sections 13000-14958) of the CWC is the Porter-Cologne Water Quality Control Act of 1970. This act regulates water pollution within California by protecting water quality and beneficial uses of all state waters. The Porter-Cologne Act is administered regionally by the State Water Resources Control Board and Regional Water Quality Control Boards (RWQCB). While administration occurs at a regional level, regulations are promulgated on a statewide level to provide consistency. Aspects of the Porter-Cologne Act are similar to federal water quality regulations and programs.

The SWRCB and regional offices have broad powers and implement the CWA through the adoption of plans and policies, the regulation of discharges, the regulation of waste disposal sites and the cleanup of hazardous materials and other pollutants. It also requires reporting of unintended discharges of any hazardous substance, sewage, or oil/petroleum product. The RWQCBs regulate discharges of water to land through the issuance of waste discharge requirements and discharges to surface waters through the NPDES permit program. The RWQCBs also prepares, implements and periodically updates their basin plans. Generally, basin plans designate beneficial uses of surface water and groundwater that should be protected, establish water quality objectives to protect beneficial uses and define an implementation program to meet water quality objectives. The RWQCBs also update the 303(d) list of impaired water bodies.

Among other things, the State Board oversees construction runoff control for projects disturbing 1 acre or more (or less than 1 acre, if part of a larger common plan of development or sale) and requires coverage under the General Permit for Storm Water Discharges Associated with Construction Activities, Order No. 2009-0009-DWQ or an individual permit for the construction activity). Prior to commencing grading, the NPDES

construction stormwater permit also requires preparation (and implementation) of a Stormwater Pollution Prevention Plan (SWPPP) that identifies potential pollution sources, runoff controls or best management practices (BMPs) for construction and post-construction activities and monitoring.

2. California Safe Drinking Water Act

In addition to the federal Safe Drinking Water Act, drinking water quality is also regulated under the State Safe Drinking Water Act (California Health and Safety Code Section 116270 *et seq.*) and associated regulations. The California regulations follow the federal regulations in adopting either the National Primary Drinking Water Regulations (NPDWRs) or more stringent maximum contaminant levels (MCLs). An MCL is the highest level of a contaminant that is allowed in drinking water. Primary MCLs are established for contaminants that affect health and are set as close as economically and technically feasible to applicable Public Health Goal (the drinking water contaminant level below which there is no known or expected risk to health, as set by the California Office of Environmental Health Hazard Assessment). (Alternatively, the 'maximum contaminant level goal,' MCLG, is used at the target for federal SDWA pollutants.) Secondary MCLs are set to protect the odor, taste and appearance of drinking water. Under the California SDWA, the California Department of Public Health is responsible for establishing MCLs.

3. CCR Title 22 - Recycled Water

Under CCR Title 22, the California Department of Health Services (DHS) and the local regional water quality control board regulate the use and quality of recycled water. The local RWQCB is the permitting authority and DHS regulates the health standards that apply to recycled water use in the state. Chapter 4 of CCR Title 22 establishes recycled water quality standards and treatment reliability criteria dependent upon the end use of recycled water to protect public health. Both secondary- and tertiary-treated wastewater can meet Title 22 standards, dependent upon the end use of the water. Utilization of recycled water for groundwater recharge is reviewed by DHS on a case-by-case basis.

4. California Urban Water Management Planning Act

Enacted in 1983, as amended, this law (CWC Sections 10610–10656) requires urban water suppliers to adopt water management plans every five years and submit those plans to DWR. Adoption of the most recent (2010) round of urban water management plans was required by July 1, 2011, with the plans were due to DWR by August 1, 2011. In their water management plans, urban water suppliers must assess whether their current and planned water supplies will be enough to meet the water demands expected during the next 20 years. The plans also consider various drought scenarios and the proper ways to respond in case of an unexpected water shortage. This law and its relationship to the Riverside County General Plan is discussed further in Section 4.19.4.D.

5. Water Conservation Act (SBX 7-7)

The Water Conservation Act of 2009 (Senate Bill X7-7, Steinberg), enacted in November 2009, includes distinct requirements related to both urban and agricultural water use. This law requires that the State of California reduce urban per-capita water use statewide by 10% by the end of 2015 and 20% by the end of 2020. DWR is required to report on progress toward meeting these urban per-capita water use goals. In addition, agricultural water suppliers must adopt agricultural water management plans by the end of 2012 and then update the plans by the end of 2015 and every five years thereafter. Through its Agricultural Water Management Planning and Implementation Program, the DWR helps water districts develop agricultural water management plans and

implement cost-effective, efficient water management practices. The urban side of this law and its relationship to Riverside County are discussed further in Section 4.19.3.G.

6. Sustainable Groundwater Management Act

The Sustainable Groundwater Management Act, which consists of three separate bills (AB 1739, SB 1168, and SB 1319), was signed into law on September 16, 2014. Groundwater is a critical element of California's water system, and accounts for 39% of the water used by cities and farms. Reliance is placed heavily on groundwater during drought and other dry conditions. Some of the state's groundwater basins are sustainability managed, but many face several challenges including overdraft, seawater intrusion, degraded water quality, land subsidence, and the decline in ecosystem services provided by the interaction of groundwater and surface water.

The three bills, AB 1739, SB 1168 and SB 1319, establish a definition of sustainable groundwater management, and require local agencies to adopt management plans for the most important groundwater basins. The central feature of these bills is the recognition that groundwater management in California is best accomplished locally. Local agencies now can assess the conditions of their local groundwater basins and take the necessary measures to prevent chronic, long term overdraft. This legislation will strengthen local management and monitoring, putting California communities on a path to become more resilient to water shortages.

The Act requires the Department of Water Resources to categorize each groundwater basin as high-, medium-, low- or very low priority by January 31, 2014. All groundwater basins designated as high- or medium-priority (in relation to the threat of overdraft) must be managed by a local groundwater sustainability agency. The agency is then responsible for implementing and managing a groundwater sustainability plan. By 2020, over drafted groundwater basins must have sustainability plans and by 2022, all other high- and medium- priority basins (not in overdraft) must also have sustainability plans. By 2040, all high- and medium- priority groundwater basins must achieve sustainability.

This legislation provides measurable objectives and milestones to reach sustainability, and a state role of limited intervention when local agencies are unable or unwilling to adopt sustainable management plans. This legislation requires that prior to general plan amendments, the local groundwater sustainability agency must review the proposed changes. The groundwater sustainability agency must then supply the planning agency with information regarding the anticipated effect of the proposed project on the groundwater sustainability plan. This act also authorizes groundwater sustainability agencies to require the registration of groundwater extraction devices and to require the installation of a measurement device in order for the management agency to regulate groundwater extraction.

~~6.~~ 7. Other California Water Supply Laws

With respect to the land use decision-making, the Urban Water Management Planning Act (CWC Section 10610 *et seq.*) and provisions of the general planning laws (CGC Section 65000 *et seq.*) relate to water supply issues. In addition to these, California law requires other types of water supply analyses to be performed in connection with certain specific types of projects. While such projects do not include general plan updates, the following is provided as background discussion regarding California's other water supply statutes.

Senate Bill 610: CWC Sections 10910–10915 (commonly referred to as Senate Bill [SB] 610 according to the enacting legislation) require the preparation of a water supply assessment (WSA) for certain projects, generally including those having a water demand equivalent to a project with 500 dwelling units or more. Under SB 610, at the time the lead agency determines a project is subject to CEQA, the agency must identify the public water system that will provide the water service and request the water provider to prepare a WSA for the project (see CWC Section 10910(b)). In preparing a WSA, if the projected water demand associated with the proposed project was accounted for in the most recently adopted urban water management plan, the public water system may incorporate information from that plan into the WSA. Generally, a WSA must include an analysis of whether the total projected water supplies available to the water provider during normal, single-dry and multiple-

dry years over the next 20-year period are sufficient to meet the projected water demand associated with the project, in addition to existing and planned future uses. Additional analysis is required if the water supplies identified to serve the project include groundwater.

Upon the water provider's adoption of the WSA, the WSA must be forwarded to the lead agency and incorporated into the CEQA document being prepared for the project (CWC Section 10911). In this case, the proposed GPA No. 960 does not constitute a project for purposes of CWC Section 10912 and, therefore, the requirement to prepare a WSA does not apply and has not been triggered. Notwithstanding this requirement, projected water demands associated with GPA No. 960 are generally accounted for in the 2010 UWMP updates prepared by the regional wholesale and local retail urban water suppliers throughout Riverside County. See Section 4.19.4 and Appendix EIR-8 for applicable agency-level information.

Senate Bill 221: Similar to the requirements of SB 610, California Government Code Section 66473.7 (commonly referred to as SB 221 according to the enacting legislation) generally requires the legislative body of a city, county or local agency to include as a condition for any tentative tract map or development agreement that includes a subdivision (defined as a residential development containing 500 or more dwelling units) a requirement that a sufficient water supply is or will be available to serve the subdivision. The availability of a sufficient water supply must be based on written verification from the public water system that will provide water service to the proposed project. As with the standard provided by SB 610, a "sufficient water supply" under SB 221 is the total water supplies available to the water provider during normal, single-dry and multiple-dry years within a 20-year projection that will meet the projected demand of the proposed subdivision, in addition to existing and planned future uses, including agricultural and industrial. The water provider's verification must be based on substantial evidence, such as water supply contracts, capital outlay programs and regulatory permits and approvals regarding the water provider's right to and capability of delivering the necessary project supply. Because proposed GPA No. 960 does not include or involve development agreements or tentative tract maps, the written verification requirements of SB 221 do not apply and have not been triggered.

C. Riverside County Regulations

1. Riverside County Ordinances

These regulations are already in effect in Riverside County and are not part of the project, GPA No. 960. Rather, these policies are considered to play a role in ensuring any potential environmental effects are avoided, reduced or minimized through their application on a case-by-case basis. The County of Riverside has existing programs in place that ensure applicable policies are imposed once a development proposal triggers a specific policy or policies. The need for specific policies is determined through subsequent site-specific CEQA analysis performed at the time of implementing project review. These measures are implemented, enforced and verified through their inclusion into project conditions of approval.

Ordinance No. 427 – Regulating the Land Application of Manure: Ordinance No. 427 generally regulates the transportation and application of manure in designated areas of Riverside County. No manure transporter shall deliver manure to a site for the purposes of disposal, land application or storage within the unincorporated areas regulated by either the Santa Ana River or San Diego Regional Water Quality Control Board unless the site's landowner has a current and valid exemption as issued by the Riverside County Agricultural Commissioner. It requires the land owner to demonstrate compliance with the "Standards for Manure Use at Approved Sites" and prohibits application of manure within 100 feet of any well, among other standards. Compliance with this ordinance protects water quality for runoff, surface water and groundwater.

Ordinance No. 457 - Building Codes and Fees: This ordinance specifies the various state and/or professional society building and construction standards by which all development approved within unincorporated Riverside County must comply. It includes specifications for use of the California Building Code, the Uniform Housing Code, the California Plumbing Code, the California Mechanical Code and the California Electrical Code, among others. Use of these codes ensures that any development or construction within Riverside County meets the necessary standards for suitability, durability, safety and so on. In terms of erosion, runoff, drainage, flood control and safety, the codes include requirements for the structural integrity of buildings and other facilities for withstanding precipitation, inundation and water flow. They also specify standards for grading, lot, roadway and drainage design to ensure that water flows (particularly runoff) are directed or channeled appropriately ways. The ordinance also imposes minimum standards for permanent erosion control and associated landscaping. It includes requirements for preparation of a Storm Water Pollution Prevention Plan (SWPPP) for construction sites, implementation of year-round best management practices (BMPs) on such sites and the monitoring and maintaining of the BMPs to ensure they continue to provide adequate stormwater flow / runoff protections, erosion protection and sediment controls, both during and after construction activities on a site. As a result, compliance with this ordinance, as required in standard Riverside County development conditions of approval, ensures adequate measures are in place to prevent adverse effects from construction and urban runoff, stormwater flows and water erosion on developed lands.

Ordinance No. 458 - Regulating Flood Hazard Areas and Implementing the National Flood Insurance Program: This ordinance was adopted pursuant to the requirements of the National Flood Insurance Program (Title 42, United States Code, Section 4001 *et. seq.,* as amended) to protect the public's health, safety and welfare from flooding hazards. It does so by regulating development within flood hazard areas and establishing a variety of land use and construction standards for such development. The ordinance includes construction standards that apply to all new structures and substantial improvements to existing structures within Riverside County's mapped Special Flood Hazard Areas and floodplains (see EIR Section 4.11). Among other requirements, these types of construction are required to: use materials resistant to flood damage; use construction methods and practices that minimize flood damage; and have electrical, heating, ventilation, plumbing and air conditioning equipment and other service facilities designed and located to prevent water from entering or affecting them during flooding.

Further, all subdivision proposals and other proposed new development, including manufactured home parks or subdivisions greater than 50 lots or 5 acres are required to design and construct all utilities and facilities, including sewer, gas, electrical, propane tanks and water systems so as to minimize or eliminate flood damage. It also requires provisions of adequate drainage and obtainment of all other required state and federal permits. All new and replacement water supply systems must be designed to minimize or eliminate infiltration of floodwaters into the systems. New and replacement sanitary sewage systems must also be designed to minimize or eliminate infiltration of floodwaters into the systems and discharges from the systems into flood waters and onsite waste disposal systems must be located to avoid impairment or causing contamination during flooding. These measures ensure that water and wastewater systems are adequately protected from flooding and would not contaminate or be contaminated by floodwaters. Thus, this ordinance serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 461 - Road Improvement Standards: While not addressing water resources directly, this ordinance does set forth standards for roads, bridges and other transportation-related facilities, including those aspects of hydrology, flood control and associated drainage functions. Because of their linear and impervious nature, paved roadways typically act as conduits for water flow, particularly stormwater (urban) runoff from developed areas. In addition, they often may function informally as barriers (dams, dikes or levees) to water flow or cause water channelization when constructed on raised beds or with tall curbs or crowns. Also, roadways often cross rivers, streams, drainages, floodplains and similar features. All crossings must be sufficiently

engineered to withstand the potential impacts of flood flows. In total, this ordinance serves to mitigate potential flooding hazards to people, property and structures by ensuring that roads and associated improvements and features are designed, constructed and maintained in a manner appropriate to the water flow potential and flooding hazard. It also serves to place to prevent significant adverse impacts due to road construction, runoff and stormwater flows from roadways, as well as water erosion.

Ordinance No. 592 – Regulating Sewer Use, Sewer Construction and Industrial Wastewater Discharges in County Service Areas: Ordinance No. 592 sets various standards for sewer use, construction and industrial wastewater discharges within Riverside County to protect both water quality and the infrastructure conveying and treating these wastewaters. Among other things, it establishes construction requirements for sewers, laterals, house connections and other sewerage facilities and for abandoned sewers, septic tanks and seepage pits in accordance with the Uniform Plumbing Code. It prohibits the discharge of rainwater, stormwater, groundwater, street drainage, subsurface drainage or yard drainage into any sewerage facility which is directly or indirectly connected to the sewerage facilities of Riverside County. Rather, these discharges must be emptied into storm drainage systems, not sanitary sewer systems.

It further protects Riverside County sewer systems and wastewater treatment facilities by prohibiting discharges (either directly or indirectly) to the county sewerage system of any of the following wastes: Gasoline, benzene, naphtha, solvent, fuel oil, flammable or explosive substances, hazardous amounts of toxic or poisonous substances, obstructive solids or viscous substances (including "asphalt, dead animals, ashes, sand, mud, straw, industrial process shavings, metal, glass, rags, feathers, tar, plastics, wood, whole blood, paunch manure, bones, hair and flesh, entrails, paper dishes, paper cups, milk containers or similar paper products, either whole or ground"), excessive concentrations of non-biodegradable oil, petroleum oil or refined petroleum products, dispersed biodegradable oils and fats, such as lard, tallow or vegetable oil in excessive concentrations that would tend to cause adverse effects on the sewerage system, excessively high concentrations of chemicals, such as cyanide, sulfides, acids, bases, chlorides, precipitates, dyes, plastics, metals, heavy metals, radioactive materials, etc., as well as "any substances that would interfere detrimentally with wastewater treatment processes, cause a public nuisance or cause any hazardous condition to occur in the sewerage system."

In short, this ordinance prohibits any discharges to any public sewer (which directly or indirectly connects to Riverside County's sewerage system) any wastes that may have an adverse or harmful effect on sewers, maintenance personnel, wastewater treatment plant personnel or equipment, treatment plant effluent quality, public or private property or may otherwise endanger the public, the local environment or create a public nuisance. As a result, this ordinance serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 617– Hazardous Substances (Regulating Underground Storage Tanks): Ordinance No. 617 implements Chapter 6.7 of the California Health and Safety Code, Sections 25280, *et seq.*, which establishes and provides for a program for the prevention of contamination from improper storage of hazardous substances stored underground. It also ensures that newly installed underground tank systems meet appropriate construction standards and that existing underground tanks systems are properly maintained, monitored and inspected to protect health, property and the public. It also establishes and a Local Oversight Program for the unauthorized releases of petroleum and petroleum-related materials from leaking underground tank systems which require remedial action and requires remediation of unauthorized releases from underground tank systems to prevent long-term threats to the public health, water quality and the environment.

Ordinance No. 629 – Prohibiting Bathing, Swimming, Boating or Entering Irrigation Canals, Ditches or Drains in Unincorporated Areas of Palo Verde Valley: Ordinance No. 629 protects water quality by making it unlawful for any person to "bathe, swim, boat, water-ski or otherwise enter into" the water in any irrigation canal,

lateral, ditch or drain in the unincorporated area of the Palo Verde Valley, coterminous with the Palo Verde Irrigation District.

Ordinance No. 650 – Sewer Discharge in Unincorporated Territory: Ordinance No. 650 protects water quality, storm drains and surface waters by prohibiting the discharge or deposition of any sewage, sewage effluent or non-hazardous waste, treated or untreated, into any streams or bodies of water above or below the ground, within Riverside County. It also makes it "unlawful for any person to install or alter plumbing facilities or drainage systems for the discharge or deposit of any sewage, sewage effluent or nonhazardous waste from any dwelling, house or building" without a permit from the County of Riverside. It requires that sewage effluent must be disposed according to the minimum standards of the most recent edition of the Uniform Plumbing Code and the sewage disposal requirements of the Riverside County Department of Environmental Health. Most importantly, it specifies that if sanitary drainage system (i.e., sewer) is not available, an 'Onsite Wastewater Treatment System' (OWTS) (an individual or community onsite wastewater treatment, pretreatment and dispersal system including, a conventional or alternative subsurface discharge) must be provided. The type of sewage facilities installed shall be determined on the basis of location, soil porosity, site slope and ground water level, and shall be designed to receive all sanitary sewage from the property.

It also includes a variety of standards related to OWTS, including: prohibition on surface drainage entering any part of the OWTS; requirements for setbacks between subsurface sewage disposal components (including septic tanks, distribution and leaching systems) and any water well; requirements that the OWTS function in a sanitary manner and not result in contamination, pollution or creation of a nuisance or endanger the safety of any domestic water supply or public health. OWTS are also subject to detailed plan review and approval, as well as pre-site and construction inspections by the County of Riverside. Thus, this ordinance serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 659 – Development Mitigation Fee for Residential Development (DIF Program): This ordinance sets a range of development impact fees to be used "in order to effectively implement the Riverside County General Plan, manage new residential, commercial and industrial development and reduce impacts caused by such development." It is intended to mitigate growth impacts (particularly those arising from population growth) on public facilities within Riverside County to ensure residents are not placed into conditions perilous to their health, safety, comfort or welfare.

The ordinance establishes the process for (and nexus to) the construction or acquisition of various types of public facilities, as well as the preservation of open space, wildlife and their associated habitats. The DIF program ensures that "all new development bear its fair share cost of providing the facilities, open space and habitat reasonably needed to serve that development." Hence the program applies to all new residential, commercial and industrial development, as well as to surface mining. Fees are assessed on the basis of regional location within Riverside County, land use type (per dwelling unit for residential units and per acre for all other uses) and the applicable categories of facilities to be provided. For transportation and flood control, fees are based on forecast development needs for the subsequent 20 years.

In regards to flood control facilities, the DIF program ensures fees are collected and expended to provide necessary facilities commensurate with the ongoing levels of development in specific areas not already subject to, or in addition to, Area Drainage Plan fees as under Ordinance No. 458. This ordinance provides mitigation for development impacts on flood control facilities and future needs for flood control by ensuring that funds are collected and utilized to provide needed facilities as development progresses within Riverside County. The provision of these facilities ensures new development does not expose people, property or structures to undue risks from drainage or stormwater flows.

Ordinance No. 682 – Construction, Reconstruction, Abandonment and Destruction of Wells: Ordinance No. 682 establishes minimum standards for construction, reconstruction, abandonment and destruction of wells in order to protect underground water resources and provide safe water within Riverside County. This ordinance is enforced by the Riverside County Department of Environmental Health. It requires county permits for construction, reconstruction or decommissioning (destruction) of various types of water wells. It also sets standards for these activities pursuant to those "recommended in the Bulletins of the California Department of Water Resources." It contains prohibitions on placing wells where sources of pollution or contamination could contaminate or pollute the well water. It also requires wells be located "an adequate distance from all potential sources of contamination and pollution," including minimums of 50 feet from sewers, 100 feet from watertight septic tanks, sub-surface sewage leach line or leach fields and animal or fowl enclosures, 150 feet from cesspools or seepage pits, and 200 feet from any surface sewage disposal system discharging 2,000 gallons per day or more. Minimum distances from other sources of pollution or contamination shall be as determined by the Department upon investigation and analysis of the probable risks involved. It also sets a variety of water quality standards for water supply wells pursuant to the standards for constituents required in the California Code of Regulations, Title 22, "Domestic Water Quality and Monitoring." All individual domestic water wells must also be tested for and meet the nitrate, fluoride and TDS (or total filterable residue) standards in Title 22. Through these means, this ordinance serves to protect water supplies, as well as water quality, for groundwater.

Ordinance No. 754 - Stormwater/Urban Runoff Management and Discharge Controls: This ordinance protects the health, safety and general welfare of Riverside County residents by imposing restrictions to reduce pollutants in stormwater discharges to the maximum extent practicable, regulating illicit connections and discharges to the storm drain system and regulating non-stormwater discharges to the storm drain system. The intent of this ordinance is to protect and enhance the water quality of Riverside County watercourses, water bodies, groundwater and wetlands in a manner pursuant to and consistent with applicable requirements contained in the federal CWA and the CWC, as well as other applicable state and federal regulations.

Among other things, the ordinance requires that all discharge to storm drain systems be confined to stormwater runoff discharged pursuant to a National Pollutant Discharge Elimination System (NPDES) permit or as otherwise authorized by the Santa Ana River, San Diego or Colorado River Basin Regional Water Quality Control Board or the State Water Resources Control Board in compliance with the Clean Water Act. This ordinance also establishes a variety of standards and BMPs associated with controlling stormwater runoff, including requirements to:

- Increase permeable areas (by leaving highly porous soil and low-lying areas undisturbed; by incorporating landscaping and open space into the project design; by using porous materials for or near driveways and walkways; and, by incorporating detention ponds and infiltration pits into the project design).

- Direct runoff to permeable areas (by orienting it away from impermeable areas and towards swales, berms, green strip filters, gravel beds or French drains; by installing rain-gutters oriented towards permeable areas; by modifying the grade of the property to divert flow to permeable areas and minimize the amount of stormwater runoff leaving the property; and, by designing curbs, berms or other structures so they do not isolate permeable or landscaped areas).

- Maximize stormwater storage for reuse (by using retention structures, subsurface areas, cisterns or other structures to store stormwater runoff for reuse or slow release).

Although focusing on the pollution-control aspects of the NPDES program, in conjunction with Ordinance No.'s 457 and 460, this ordinance establishes a range of standards and permit requirements that collectively serve to ensure that flooding, stormwater flows and runoff are managed appropriately to protect water quality and water

infrastructure and prevent risks to people, property, structures and facilities within Riverside County. By requiring specific standards for development and establishing a program for the approval, implementation and verification of such measures, this ordinance mitigates potential hazards that could arise from stormwater flows and runoff, including flooding and erosion, and its effects on water quality and water infrastructure.

Ordinance No. 830 – Regulating the Land Application of Class A Sewage Sludge for Agricultural Activities: Ordinance No. 830 regulates the application of bulk Class A sewage sludge in commercial farming uses to ensure it does not adversely affect public health, ground and surface water or soils. Through these regulations, this ordinance serves to protect water supplies and water quality for both surface water and groundwater.

Ordinance No. 843 – Regulating the Discharge of Wastes into the Public Sewer System for the Highgrove Community: Ordinance No. 843 regulates the discharge of wastes into the sewage collection systems of the Highgrove community as these effluents are channeled to the City of Riverside's Regional Water Quality Control Plant (RWQCP) and ultimately discharged into permeable soil and/or surface waters of the Santa Ana River. The purpose of this regulation is to: establish sewage effluent discharge limitations and requirements that comply with federal general pretreatment regulations (as stated in Section 403.2 of Title 40 of the Code of Federal Regulations); ensure water reaching the RWQCP does not interfere with the operation of the plant; prevent the introduction of pollutants into the RWQCP from the Highgrove community; improve opportunities to recycle and reclaim municipal and industrial wastewater and biosolids from the Highgrove community; and enable the City of Riverside to comply with its NPDES Permit conditions, biosolids use and disposal requirements and any other federal or state laws to which the RWQCP is subjected. This ordinance also addresses the issuance of Industrial User permits; monitoring, compliance and enforcement activities; administrative review procedures; industrial waste plan check review services; and, user reporting requirements. Thus, this ordinance serves to protect water supplies, water and wastewater facilities, and water quality for both surface water and groundwater.

Ordinance No. 856 – Establishing a Septic Tank Prohibition for Specified Areas of Quail Valley and Requiring the Connection of Existing Septic Systems to Sewer: Ordinance No. 856 was enacted to protect the water quality of groundwater in the Quail Valley region of Riverside County. It prohibits new septic systems and expansions or modifications of existing septic systems within the region because of the unacceptable number of septic system failures leading to surface discharges of untreated sewage and its mixing with other run-off water, directly affecting the area's residents and polluting runoff water during rain events. Further, stormwater runoff from this area drains almost directly into Canyon Lake, which is listed by the USEPA as an impaired water body due to excessive concentrations of bacteria, nitrogen and phosphorus, all of which are present in septic wastes.

This prohibition was also necessary pursuant to the Uniform Plumbing Code, referenced as Riverside County's standard for plumbing design and installation by Riverside County Ordinance No. 457, and which states in Appendix K, Section (g) "When there is insufficient lot area or improper soil conditions for adequate sewage disposal for the building or land use proposed, no building permit shall be issued and no private sewage disposal shall be permitted." The prohibitions and restrictions of this ordinance serve to protect water supplies, water and wastewater facilities, and water quality for both surface water and groundwater in the Quail Valley region, as well as Canyon Lake and the water users relying on it as a water supply source.

Ordinance No. 859 - Water-Efficient Landscape Requirements: Adopted in 2006, this ordinance outlines water-efficient landscape standards for development within Riverside County in order to implement requirements of the California Water Conservation in Landscaping Act of 2006 and the California Code of Regulations Title 23, Division 2, Chapter 2.7. It includes a number of measures designed to conserve water, including: provisions for water management practices and water waste prevention; establishment of a structure for planning, designing,

installing, maintaining and managing water-efficient landscapes in new and rehabilitated projects; reducing water demands from landscapes without adversely affecting landscape quality or quantity; requirements for landscapes not exceeding a maximum water demand of 70% of its reference evapotranspiration (ETo) or any lower percentage required by state legislation; elimination of water waste from overspray and/or runoff; and, education of the public regarding the benefits of landscape water conservation. It includes a number of standards, including planting plan requirements, irrigation design plan requirements, soil management plan requirements, grading design plan requirements and landscape irrigation and maintenance measures. By conserving water, this ordinance protects existing water supplies (surface and groundwater). And by limiting water applications, it also helps minimize water runoff and water erosion in landscaped areas.

Ordinance No. 871 – Prohibiting the Installation of Specified Septic Tank Systems in Cherry Valley: Ordinance No. 871 was enacted to protect water quality in the Cherry Valley region of Riverside County from high nitrate levels in drinking water as a result of failing septic systems. Thus, this ordinance prohibits new septic systems and expansions or modifications of existing septic systems within the region because of septic system failures likely contributing to excessive nitrate levels in the region's groundwater. Only septic system designs that can effectively reduce (i.e., 50% or more) effluent nitrate levels and not lead to further degradation of the groundwater shall be approved by the County of Riverside. Through these limitations, this ordinance protects water supplies and groundwater quality.

2. Riverside County Flood Control and Water Conservation District (FCWCD)

The FCWCD was created in 1945 by act of state legislature in order to protect the people, property and watersheds of Riverside County from damage or destruction from flood and stormwater, and to conserve, reclaim and save such waters for beneficial use. The District encompasses 2,700 miles of western Riverside County and extends easterly into the Coachella Valley to include the cities of Palm Springs, Cathedral City and Desert Hot Springs. (East of this, flood control functions are performed by the Coachella Valley Water District.) The FCWCD is governed by a board, comprised of Riverside County's Board of Supervisors. The District also manages Riverside County's Master Drainage Plans and Area Drainage Plans. See Section 4.19.2.E.5 for more information on these.

Functionally, the District provides a number of services, including: identification of flood hazards and problems; regulation of floodplains, *regulation of* drainage and development; ~~planning for~~ county watercourse~~s~~ and drainage *planning*; education for flood prevention and safety; construction of flood control structures and facilities; flood warning and early detection; and, maintenance and operation of county flood control structures. The District also provides certain non-tax supported functions, such as floodplain management, development review, NPDES compliance, etc., for ~~the~~ *portions of the* ~~entire~~ county. And unlike County of Riverside departments, the FCWCD has the authority to expend tax dollars within city boundaries as well as within unincorporated areas.

3. Flood Control Authority for Eastern County - Coachella Valley Water District

For a variety of reasons, within the Coachella Valley, county flood control oversight responsibilities rests with the Coachella Valley Water District (CVWD) rather than the FCWCD. (Though FCWCD remains responsible for the rest of Riverside County.) The CVWD oversees flood protection for nearly 600 square miles. This includes 16 stormwater protection channels within a system that encompasses roughly 135 miles of channels built along the natural alignments of dry creeks that naturally flow from the surrounding mountains, down onto the Coachella Valley and, ultimately, into the Whitewater River.

In addition, a number of dikes and levees have also been designed and built to collect rapidly flowing flood water, mostly in the 'cove communities.' This is an important element for regional flood control, even though the area is desert with an average of only 3 inches or rainfall a year. Since this moisture can occur all at once as heavy rains falling in the valley, or even more perilously in the extremely tall San Jacinto Mountains to the west, severe floods – particularly flash floods – are a hazard to the region.

On its website, the CVWD describes the "backbone of the stormwater protection system" as 50-mile storm channel that runs from the Whitewater area north of Palm Springs to the Salton Sea. The western half of the channel runs along the natural alignment of the Whitewater River that cuts diagonally across the valley to Point Happy in La Quinta (near Highway 111 and Washington Street). Because the riverbed flattens out naturally in the eastern valley, downstream from Point Happy a man-made storm channel funnels flood waters to the Salton Sea. The entire length of this flood protection facility is known as the Whitewater River/Coachella Valley Stormwater Channel. The channel was built to withstand a 'standard project flood' (which is greater than a 100-year flood) or approximately a flow of 80,000 cubic feet per second.

Stormwater protection is funded primarily from local property taxes. Unfortunately, this limits expansion of the stormwater system. The CVWD reports that the Thousand Palms area and rural areas in the eastern Coachella Valley from Oasis to Salton City do not currently have flood protection, although the District is working with federal agencies to expand flood protection to these areas.

D. Existing General Plan Policies

These regulations are already in effect in Riverside County and are not part of the proposed project, GPA No. 960. Rather, these policies are those considered to play a role in ensuring any potential water-related environmental effects are avoided, reduced or minimized through their application on a case-by-cases basis when a given development proposal warrants their use.

1. Open Space (OS) Element

Policy OS 1.1: Balance consideration of water supply requirements among urban, agricultural and environmental needs so that sufficient supply is available to meet each of these different demands.

Policy OS 1.2: Develop a repository for the collection of county water resource information.

Policy OS 1.3: Provide active leadership in the regional coordination of water resource management and sustainability efforts affecting Riverside County and continue to monitor and participate in, as appropriate, regional activities addressing water resources, groundwater and water quality, such as groundwater management plans, to prevent overdraft caused by population growth.

Policy OS *2.2* **(Previously 2.1):** Encourage the installation and use of water-conserving systems such as dry wells and graywater systems, where feasible, in new developments. The installation of cisterns or infiltrators shall be encouraged to capture rainwater from roofs for irrigation in the dry season and flood control during heavy storms.

Policy OS 2.5: Encourage continued agricultural water conservation measures and recommend the following practices where appropriate and feasible: lining canals, recovering tail water at the end of irrigated fields and appropriate scheduling of water deliveries.

Policy OS 3.1: Encourage innovative and creative techniques for wastewater treatment, including the use of local water treatment plants.

Policy OS 3.2: Encourage ~~innovative~~ *wastewater treatment* ~~techniques~~ *innovations, sanitary sewer systems, and groundwater management strategies that protect groundwater quality in rural areas.*

Policy OS 3.3: Minimize pollutant discharge into storm drainage systems, natural drainages and aquifers.

Policy OS 4.1: Support efforts to create additional water storage where needed, in cooperation with federal, state and local water authorities. Additionally, support and/or engage in water banking in conjunction with these agencies where appropriate, as needed.

Policy OS 4.2: Participate in the development, implementation and maintenance of a program to institute recharge aquifers underlying the county. The program shall make use of flood and other waters to offset existing and future groundwater pumping, except where:

a. The quality of groundwater resources would be reduced;

b. The available groundwater aquifers are full; or

c. Rising water tables threaten the stability of existing structures.

Policy OS 4.3: Ensure that adequate aquifer water recharge areas are preserved and protected.

Policy OS 4.4: Incorporate natural drainage systems into developments where appropriate and feasible.

Policy OS *4.8* **(Previously 4.6):** Use natural approaches to managing streams to the maximum extent possible, where groundwater recharge is likely to occur.

Policy OS 5.1: Substantially alter floodways or implement other channelization only as a 'last resort,' and limit the alteration to:

a. That necessary for the protection of public health and safety only after all other options are exhausted;

b. Essential public service projects where no feasible construction method or alternative project location exists; or

c. Projects where the primary function is improvement of fish and wildlife habitat.

Policy OS 6.1: During the development review process, ensure compliance with the Clean Water Act's Section 404 in terms of wetlands mitigation policies and policies concerning fill material in jurisdictional wetlands.

Policy OS 6.3: Consider wetlands for use a natural water treatment areas that will result in improvement of water quality.

2. Land Use (LU) Element

Policy LU 5.2: Monitor the capacities of infrastructure and services in coordination with service providers, utilities and outside agencies and jurisdictions to ensure that growth does not exceed acceptable levels of service.

Policy LU 5.3: Review all projects for consistency with individual urban water management plans.

Policy LU *9.2* **(Previously 8.2):** Require that development protect environmental resources by compliance with the Multipurpose Open Space Element of the General Plan, and federal and state regulations such as CEQA, NEPA, the Clean Air Act and the Clean Water Act.

Policy LU *21.2* **(Previously 17.2):** Require that adequate and available water resources exist to meet the demands of the proposed land use [within the Rural Foundation].

Policy LU *28.3* **(Previously 22.3):** Require that adequate and available circulation facilities, water resources and sewer facilities exist to meet the demands of the proposed residential land use.

Policy LU *29.7* **(Previously 23.7):** Require that adequate and available circulation facilities, water resources, and sewer facilities exist to meet the demands of the proposed [commercial] land use.

Policy LU *30.7* **(Previously 24.7):** Require that adequate and available circulation facilities, water resources and sewer facilities exist to meet the demands of the proposed [industrial] land use.

Policy LU *31.4* **(Previously 25.4):** Require that adequate and available circulation facilities, water resources and sewer facilities exist to meet the demands of the proposed [public facility] land use.

Policy LU *32.6* **(Previously 26.6):** Require that adequate and available circulation facilities, water resources and sewer facilities exist to meet the demands of the proposed [community center] land use.

Policy LU *34.3* **(Previously 28.4):** Require that adequate and available *transportation* ~~circulation~~ facilities, water resources, sewer facilities and/or septic capacity exist to meet the demands of the proposed [Rural Village Overlay] land use.

E. Proposed New or Revised County General Plan Policies

Except to the extent they have been amended as part of GPA No. 960, the General Plan policies described above continue to apply. The following are proposed new or revised General Plan polices address impacts related to water resources.

1. Open Space (OS) Element

NEW **Policy OS 1.4:** *Promote the use of recycled water in landscape irrigation.*

NEW **Policy OS 2.1:** *Implement a water-efficient landscape ordinance and corresponding policies that promote the use of water-efficient plants and irrigation technologies, minimizes the use of turf, and reduces water waste without sacrificing landscape quality.*

Policy OS 2.3: ~~Encourage native, drought-resistant landscape planting.~~ *Seek opportunities to coordinate water-efficiency policies and programs with water service providers.*

Policy OS 2.4: Support and engage in educational outreach programs with other agencies, *the public, homebuilders, landscape installers and nurseries that* promote water conservation and wide-spread use of water-*efficient* ~~saving~~ technologies.

NEW **Policy OS 3.4:** *Review proposed projects to ensure compliance with the National Pollutant Discharge Elimination System (NPDES) Permits and require them to prepare the necessary Stormwater Pollution Prevention Program (SWPPP).*

NEW **Policy OS 3.5:** *Integrate water runoff management within planned infrastructure and facilities such as parks, street medians and public landscaped areas, parking lots, streets, etc., where feasible.*

NEW **Policy OS 3.6:** *Design the necessary stormwater detention basins, recharge basins, water quality basins or similar water capture facilities to protect water-quality. Such facilities should capture and/or treat water before it enters a watercourse. In general, these facilities should not be placed in watercourses unless no other feasible options are available.*

NEW **Policy OS 3.7:** *Where feasible, decrease stormwater runoff by reducing pavement in development areas, reducing dry weather urban runoff and by incorporating 'Low Impact Development,' green infrastructure and other Best Management Practice design measures, such as permeable parking bays and lots, use of less pavement, biofiltration and use of multi-functional open drainage systems.*

NEW **Policy OS 4.5:** *Encourage streets in a vicinity of watercourses to include park strips or other open space areas that allow permeability.*

Policy OS *4.6* **(Previously 4.5):** Retain stormwater at or near the site of generation for percolation into the groundwater to conserve it for future uses and to mitigate adjacent flooding. *Such retention may occur through 'Low Impact Development' or other Best Management Practice measures.*

NEW **Policy OS 4.7:** *Encourage stormwater management and urban runoff reduction as an enhanced aesthetic and experience design element. Many design practices exist to accomplish this depending on site conditions, planned use, cost-benefit and development interest.*

NEW **Policy OS 4.9:** *Discourage development within watercourses and areas within 100 feet of the outside boundary of the riparian vegetation, the top of the bank or the 100-year floodplain, whichever is greater.*

Policy OS 5.2: If substantial modification to a floodway is proposed, design it to reduce adverse environmental effects to the maximum extent feasible, considering the following factors:

a. Stream scour;

b. Erosion protection and sedimentation;

c. Wildlife habitat and linkages;

d. *Cultural resources including human remains;*

~~d~~ *e.* Groundwater recharge capability;

~~e~~ *f.* Adjacent property; and

~~f~~ *g.* Design (a natural effect, examples could include soft riparian bottoms and gentle bank slopes, wide and shallow floodways, minimization of visible use of concrete and landscaping with native plants to the maximum extent possible). A site-specific hydrology study may be required.

Policy OS 5.3: Based upon site-specific study, all development shall be set back from the floodway boundary a distance adequate to address the following issues:

a. Public safety;

b. Erosion;

c. Riparian or wetland buffer;

d. Wildlife movement corridor or linkage; *and/or*

e. Slopes.*;*

f. Type of watercourse; and

g. Cultural resources.

Policy OS 5.5: ~~New development shall~~ *P*reserve and enhance existing native riparian habitat and prevent obstruction of natural watercourses. ~~Incentives shall be utilized to the maximum extent possible.~~ *Prohibit fencing that constricts flow across watercourses and their banks.*

2. Land Use (LU) Element

Policy LU *7.2* **(Previously 6.2):** Notwithstanding the Public Facilities designation, public facilities shall also be allowed in any other land use designation except for the Open Space-Conservation and Open Space-Conservation Habitat land use designations. For purposes of this policy, a public facility shall include all facilities operated by the federal government, State of California, County of Riverside, any special district governed by *or operating within* the County of Riverside or any city, and all facilities operated by any combination of these agencies.

Policy LU *9.1* **(Previously 8.1):** Provide for permanent preservation of open space lands that contain important natural resources, *cultural resources,* hazards, water features, watercourses *including arroyos and canyons*, and scenic and recreational values.

Policy LU *9.4* **(Previously 8.4):** Allow development clustering and/or density transfers in order to preserve open space, natural resources, *cultural resources*, and/or biologically sensitive resources. *Wherever possible, development on parcels containing 100-year floodplains and blue line streams and other higher-order watercourses and areas of steep slopes adjacent to them shall be clustered so as to keep development out of the watercourse and adjacent steep slope areas, and to be compatible with other nearby land uses.*

NEW **Policy LU 18.1:** *Ensure compliance with the County's water-efficient landscape policies. Ensure that projects seeking discretionary permits and/or approvals develop and implement landscaping plans prepared in accordance with the Water-Efficient Landscape Ordinance (Ordinance No. 859), the County of Riverside Guide to California Friendly Landscaping and Riverside County's California Friendly Plant List. Ensure that irrigation plans for all new development incorporate weather-based controllers and utilize state-of-the-art water-efficient irrigation components.*

NEW **Policy LU 18.2:** *Minimize use of turf. Minimize the use of natural turf in landscape medians, front-yard typical designs, parkways, other common areas, etc., and use drought tolerant planting options, mulch or a combination thereof as a substitute. Limit the use of natural turf to those areas that serve a functional recreational element. Incorporate other aesthetic design elements such as boulders, stamped concrete, pavers, flagstone, decomposed granite or manufactured-rock products to enhance visual interest and impact.*

NEW **Policy LU 18.3:** *Design and field check irrigation plans to reduce runoff. Emphasize the use of subsurface irrigation techniques for landscape areas adjoining non-permeable hardscape. Utilize subsurface irrigation or other low-volume irrigation technology in association with long, narrow or irregularly shaped turf areas. Minimize use of irregularly shaped turf areas.*

NEW **Policy LU 18.4:** *Coordinate county water-efficiency efforts with those of local water agencies. Support local water agencies' water conservation efforts.*

NEW **Policy LU 18.5:** *Emphasize and expand the use of recycled water in conjunction with local water agencies. Recycled water determined to be available pursuant to Section 13550 of the California Water Code shall be used for appropriate non-potable uses whenever it: a) provides a beneficial use to the customer; b) is economically and technically feasible; c) is consistent with applicable regulatory requirements; and, d) is in the best interests of public health, safety and welfare. With the exception of non-common areas of single-family home residential developments, all other irrigation systems must be designed and installed to accommodate the current or future use of recycled water for irrigation. If no recycled water availability exists or is imminent in the vicinity of a project (as determined by prevailing water agency), all subsurface piping shall be installed as 'recycled water ready' to reduce future retrofit costs. Such irrigation plans shall be developed in accordance with standards and policies of the applicable recycled water purveyor. Recycled water systems shall be designed to meet regulatory requirements of the California Department of Public Health and the local recycled water purveyor.*

NEW **Policy LU 18.6:** *Encourage Public Participation in Water Conservation Efforts. More outreach is needed to change the public perception of water efficient landscaping and the design and care of such landscapes as they are a departure from that 'green' paradigm with which many county residents are familiar. To achieve this objective the County will:*

a. Develop tools designed to assist landowners with converting to attractive, drought tolerant landscapes.

b. Participate in outreach efforts designed to educate developers, landscape personnel, nurseries, retail establishments and the public on water-efficient landscaping and wise water-use programs.

c. Promote the use of drought tolerant plants and irrigation components.

NEW **Policy LU 22.2:** *Require that adequate and available circulation facilities, water resources, sewer facilities and/or septic capacity exist to meet the demands of the proposed land use.*

NEW **Policy LU 22.8:** *An amendment from the Rural Community Foundation Component that meets the following criteria may be considered as an entitlement/policy amendment and processed as defined in Section 2.4 of Ordinance No. 348:*

a. This amendment shall be located within a city's sphere of influence area.

b. This amendment shall be located within an existing community that is characterized by lots smaller than 20,000 square feet in net area.

c. There shall be a memorandum of understanding between the County and the city that ensures adequate infrastructure, including sewer services for the establishment of lots smaller than one acre.

d. This amendment shall be processed with a tract or parcel map and approved with a condition of approval that requires the extension of a sewer line.

3. Circulation (C) Element

NEW **Policy C 20.5:** *In order to protect the watershed, water supply, groundwater recharge and wildlife values of watercourses, the County will avoid siting utility infrastructure and associated grading, fire clearance and other disturbances within or adjacent to watercourses, if there are feasible alternatives available and discourage special districts and other governmental jurisdictions outside of the County's authority from doing so. Where such watershed utility siting locations cannot be avoided, the impacts on watercourses shall be minimized.*

4.19.6 Thresholds of Significance for Water Resources

The proposed project would result in a significant impact related to water resources if it would:

A. Result in water supplies insufficient or unavailable to serve the project from existing entitlements and resources, or result in the need for new or expanded entitlements.

B. Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted).

C. Substantially degrade water quality.

D. Violate any water quality standards or waste discharge requirements.

E. Exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board.

F. Result in a determination by a wastewater treatment provider which serves or may serve the project that it would not have adequate capacity to serve the project's projected demand in addition to the provider's existing commitments.

G. Require or result in the construction of new water or wastewater facilities or expansion of existing facilities, the construction of which could cause significant environmental effects.

H. Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on- or off-site.

I. Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff.

J. Require or result in the construction of new stormwater drainage facilities or the expansion of existing facilities, the construction of which could cause significant environmental effects.

It should be noted that this water resources chapter collects all water-related issues into a single chapter. Specifically, the above threshold questions are arranged to group them by topic: water supply (questions A and B), water quality (C and D), infrastructure (E, F and G) and hydrology (H, I and J). In contrast, the CEQA Appendix G, "Environmental Checklist Form," included with the State CEQA Guidelines organizes the water

topics slightly differently. Questions A, E F, G and J are from checklist category XVII (Utilities and Service Systems); the remaining questions (B, C, D, H and I) are from category IX (Hydrology and Water Quality). The remaining Appendix G questions from category IX address flooding hazards and related safety risks. These are addressed in Section 4.11 (Flooding and Dam Inundation) of this EIR. The remaining category XVII questions, which address landfills and solid waste, are included in Section 4.17 (Public Facilities) of this EIR.

4.19.7 Effect of GPA No. 960 on the General Plan and on Water Resources

The proposed update to the General Plan pursuant to GPA No. 960 includes land use overlays, land use designation (LUD) changes and new or revised policies that would allow for the conversion of rural, semi-rural, agricultural and vacant lands into suburban or urban uses in concentrated areas throughout Riverside County. As with the current General Plan, future development consistent with GPA No. 960 has the potential to introduce people, property and structures into previously undeveloped areas. The resultant growth population (from new residential uses) and jobs and economic activity (from commercial, industrial and institutional uses) would result in a corresponding increase the amount of water used and wastewater generated by these various uses. This section examines the proposed changes in the General Plan and the effects on water and wastewater that would result from these changes.

A. Proposed Changes to the General Plan

As part of the update process, water resource data in the General Plan was updated and water-related policies reviewed and revised where necessary. The existing General Plan addresses water resources directly in the Multi-purpose Open Space and Conservation (OS-C) Element, as well as in various locations within the Land Use Element. In particular, the OS-C Element includes the following updates under GPA No. 960.

Protection of Arroyos: Text was added to the OS-C Element and elsewhere to increase awareness and protection of this unique water resource. Policies OS 5.3 and 5.5 were revised as a result.

Water Supply and Conveyance: The existing information in the OS-C Element was updated on this topic, including the addition of information on recent changes (lawsuits, species protections, etc.) affecting SWP water availability. A new policy, OS 1.4, was added.

Water Conservation: Existing information on this topic in the OS-C Element was updated and expanded, particularly relating to Riverside County's water-efficient landscaping ordinance and program (reflected in changes in the Land Use Element also). Policies OS 2.1 (now 2.2), 2.3 and 2.4 were revised and new policies were added to both the OS-C and Land Use Elements: OS 2.1, LU 18.1, 18.2, 18.3, 18.4, 18.5 and 18.6.

Water Quality: Existing information in the OS-C Element on this topic was updated and expanded, particularly with respect to non-point source pollution. New policies, OS 3.4, 3.5, 3.6 and 3.7, were added and one policy, OS 2.2, was deleted.

Groundwater Recharge: Additions were made to the OS-C Element to expand upon this topic, particularly as related to Best Management Practices (BMPs). New policies, OS 4.5, 4.7 and 4.9, were added, one policy, OS 4.7, was deleted and two policies were revised – OS 4.5 (now 4.6) and OS 4.6 (now 4.8).

Watercourse Overlays: Text and policies related to this overlay type were deleted; including Policy LU 28.1 and the 'Watercourse Overlay' description in the land use category tables throughout the General Plan and Area Plans.

Water Infrastructure: Additions were made to clarify and reinforce General Plan policies for ensuring adequate infrastructure, including water and sewer conveyances, are provided for new development as needed. New policies, LU 22.2, 22.8 and 20.5 were added and one policy, LU 6.2 (now 7.2), was revised.

In addition to these changes, a variety of LUD and policy area changes are proposed, as per the descriptions in Section 3.0 of this EIR and associated EIR Figure 3-1 (and corresponding maps within each Area Plan) that may indirectly affect water resources. Changes to specific lands would affect the specific hydrology on or underlying the site. Where such changes would lead to an increase or decrease in development potential (density or intensity), the demand for potable water associated with new residents, visitors and workers would also be altered correspondingly.

GPA No. 960 also includes new and revised policies which would be implemented at a future time in locations not foreseeable at present; for example, the new incidental rural Retail-Commercial policy, Indian fee land policies, as others as described in Section 3.0 of the EIR. Similarly, new maps for trails and county roads (GP Figures C-7 and C-1, plus corresponding maps within each Area Plan) indicate general road and trail alignments, but not specific locations since specific design and construction sites must be determined based on specific site topography, existing development and timing, as well as both existing and future levels of service to be met. Actual locations for these improvements will be determined based on site assessment of opportunities and constraints to determine environmentally preferred alignments to minimize adverse effects. Also, normally such improvements are generally not proposed until either specific new developments or overall growth within the area triggers their need. As such, the spatial effects of these future trails and roads on specific hydrology or watersheds are not presently foreseeable. Rather, they will require site-specific analyses and mitigation when proposed as part of future development to occur as the General Plan builds out. As such, future impacts and mitigation will be assessed programmatically pursuant to the performance standards outlined herein, as well as elsewhere throughout this EIR.

B. Analysis of GPA No. 960 Effects on Water Resources

1. Water Data and Calculations

Because water resources are such a highly regulated and contentious issue, myriad documents and data sources are available addressing every possible aspect of the resource. The topic of water resources covers a wide array of topics and information. For the purposes of this portion of the EIR, however, they can be summarized into four key groups of topics, as follows:

Hydrology: Watershed, groundwater basins and surface drainages. In regards to existing resources, existing hydrology is described in Section 4.19.2.B, existing groundwater basins are described in Section 4.19.4.B and existing water quality is described in Section 4.19.2.C, as well as elsewhere throughout the chapter. In terms of future resources, effects of long-range development and General Plan build out on hydrology cannot be reasonably foreseen with any specificity at this time. Accordingly, effects of future development accommodated by the project, GPA No. 960, would have to be addressed programmatically pursuant to the previous EIR certified for the 2003 General Plan (i.e., EIR No. 441) as well as this EIR. However, for project components with known spatial locations, potential effects on hydrology can be roughly estimated in terms of amounts of acreages affected within each hydrological region, watershed or groundwater basin. Towards that end, this data is presented in Table 4.19-BO (Summary of Project Spatial Effects on Hydrology, by Water District), below, at the

end of this subsection. In some cases, future development sites may be located within an existing Riverside County Master Drainage Plan (MDP). See Table 4.19-BP (Summary of Project Spatial Effects to Areas Outside Water Districts). In these locations, any stormwater drainage systems or other surface flow modifications required as part of the development would have to conform to the requirements of the applicable MDP.

Water Services: This category applies to the water districts, infrastructure and services provided. In regards to existing resources, water supply information on imported water is presented in Section 4.19.3.A, in particular, as well as in Section 4.19.3.B and, for future imported supplies, Section 4.19.3.C. Existing local supplies are discussed in Section 4.19.4.B for groundwater supplies and Section 4.19.4.C for other local supplies (surface, recycled, desalinated, etc.). The local supply sections also provide information on the local agencies' services, including potable, non-potable and agricultural water supplies, as well as wastewater (sewage) disposal and treatment. Regarding effects on water supplies and infrastructure, in addition to hydrology, Table 4.19-BO also shows the acreage of known spatial changes associated with the project broken down by existing water districts as well.

Water Demand: A variety of information is provided throughout this chapter regarding existing water demand. Projections for imported water demand are provided in Section 4.19.3.C and projections for local areas, by the water districts that serve them, are presented in Sections 4.19.4.E through 4.19.4.I. In addition, three tables of water calculations are presented below to address the theoretical water usage associated with the known spatial components of GPA No. 960. Only potable water (M&I) usage was calculated; no agricultural, recycled or non-potable water usages were calculated for several reasons. First, the disparity in water usage between irrigated croplands compared to dryland wheat crops (which, for example, are not irrigated) or unirrigated pastures, ranchlands, etc. The land use data available for these calculations does not provide sufficient resolution to distinguish these. Also, as noted under the water district summaries, some districts have recycled water available and some do not. Likewise, some provide non-potable water and some do not. Lastly, as with agriculture, similar data was also unavailable to differentiate between recreational uses featuring irrigated turf (e.g., developed parks, golf courses, etc.) and non-irrigated (museums and interpretive centers, bike and skate parks, lake front areas, etc.).

The existing theoretical water usage based on the identified existing use on the land is presented in Table 4.19-BI (Theoretical Water Supply for Existing and Build Out Conditions). Theoretical calculations were used because locating water usage records for each parcel within Riverside County potentially affected by GPA No. 960 was infeasible and such calculations allow for standardized assessment of existing and future demands. Projections were also made for the same locations as they would be if developed to build out pursuant to the LUDs, policy areas and other spatial changes to the General Plan foreseeable at this time. These data are presented in Table 4.19-BK (Theoretical Water Supply for Areas of New Development Potential). Lastly, Table 4.19-BM (Comparison of Existing General Plan and Proposed Updated General Plan Theoretical Water Demands at County Build Out) presents a summary of how water demand would change from existing (baseline) conditions to project build out conditions if GPA No. 960 were approved and implemented fully (i.e., 100% build out).

Wastewater / Sewer Services: Because of its close connection to water supply, many water districts also handle wastewater (sewer) services as well – its collection and/or treatment. Thus, a variety of information regarding wastewater is included under the various local agency descriptions presented in Sections 4.19.4.E through 4.19.4.I. Focused discussion of sewer services is presented under Section 4.19.4.J, including water district/agency projections related to existing sewer capacities and future demands. In addition, three table of calculations are presented below to address the theoretical generation of wastewater (i.e., sewage) associated with the known spatial components of GPA No. 960. Existing theoretical wastewater generation based on the identified existing use of land is presented in Table 4.19-BJ (Theoretical Wastewater Generated by Existing and Build Out Conditions). Theoretical calculations were used because locating sewer records for each parcel within Riverside County potentially affected by GPA No. 960 was infeasible and such calculations allow for standardized assessment of existing and future demands.

Wastewater generation projections were also made for the same locations as they would be if developed to build out pursuant to the LUDs, policy areas and other spatial changes to the General Plan foreseeable at this time. See Table 4.19-BN (Comparison of Existing General Plan and Proposed Updated General Plan Theoretical Wastewater Generations at County Build Out). The table also compares how wastewater generation would change from existing (baseline) conditions to project build out conditions if GPA No. 960 were approved and implemented fully (i.e., 100% build out).

It should be noted that these calculations assume wastewater is generated at all developed/ developable locations. That is, no reductions were assumed, even for areas in which no sanitary sewer connection was available; it was assumed for the purposes of these calculations that septic systems (OWTS) would be used for disposal. In reality, actual availability of OWTS is based on a number of factors, including geology, soils, water table levels, etc., and cannot be assumed to be available in all cases.

2. Methodology

To determine the scope of project effects, Riverside County GIS performed spatial analysis of the available water resource data by overlaying it with known project components to determine acreage within each. The results for each of these existing resources within Riverside County are summed up in the tables that follow. The theoretical water supply needs associated with the known spatial components of the project are presented in Tables 4.19-BG, 4.19-BI and 4.19-BK. Tables 4.19-BH, 4.19-BJ and 4.19-BL do the same for wastewater generation. For all of these tables, the spatial project components were sorted into three categories based on their potential to affect hydrology, water supply and generate wastewater, as follows:

'Conserved' Areas: These are areas are where project changes would result in the *removal* of a site's development potential – specifically, where the site's LUD would be changed to OS-CH for habitat conservation. In these areas, future water usage and wastewater generation is assumed to be zero since no development would generally be allowed at these locations. Similarly, no land disturbances or changes to hydrology are assumed.

'Neutral' Areas: These are parcels where project changes would result in either no net change or a *decrease* in development potential, but future development would still be permitted at some level (and assumed to occur at 100% build out for the purposes of this EIR analysis, to ensure a worst-case scenario is evaluated). As such, the associated water demand is expected to be the similar to or possibly less than that currently assumed for the given area, use and build out population in the applicable water district's urban water management plan (if applicable). Accordingly, the water use associated with these areas is assumed to be consistent with the water agency's 2010 UWMP (if any) since, by definition such plans must account for future growth and GPA No. 960 would not adversely alter (i.e., increase) such growth projections. Wastewater generation rates and disposal needs are likewise assumed to be similar or less than those previously proposed.

'Potentially Affected' Areas: These are areas where proposed project changes would result in *new* effects to hydrology, water supply and wastewater treatment because GPA No. 960 would be *increasing* the site's development potential or intensity. This includes changes that would allow future development in areas not subject to development under the existing General Plan, as well as in areas previously planned for *less* dense/intense development. The resultant growth in these areas represents new demands on water supplies and would increase demand for both water and sewer services. It would also result in topographic and other changes that would adversely affect hydrology.

Once these three categories were established per above and sorted by existing and proposed land uses, theoretical existing and future (build out) acreages, water demands and wastewater generation could be calculated, as could the extent of hydrological changes expected. Existing uses were based on visual inspection and assessment of

aerial data. Future uses were assigned per the mid-point methodology and factors outlined in General Plan Appendix E-1. See Section 4.1 of this EIR for additional methodology information.

Again, it is important to note that such calculations are specific to this EIR and are used specifically to permit comparison between 'baseline' and future water use and wastewater generation to demonstrate areas of potential impacts and the relative degree of such impacts. These data should *not* be construed as the actual water needs or sewer usage for a given location or its future development. Each water and sewer district uses its own methods, formulae and factors, which are neither available nor practicable for calculating for this programmatic EIR. Such specific information is typically provided by the associated district when an implementing development is proposed and addressed with project-specific CEQA analysis and impacts mitigation, if needed, at that time. In particular, see discussions under "SB 610" in Section 4.19.5 for more details on the site-specific water supply assessments to be provided by water districts as part of Riverside County's review and approval process for new development.

The results of the theoretical calculations are presented in the tables that follow. The significance of these effects and their impacts, as well as any mitigation applicable or needed, is discussed in the subsequent section. Relevant supporting documentation is provided in Appendix EIR-8.

3. Results

The following tables summarize projected existing and future water usage and wastewater generation rates based on baseline (existing) conditions and various build out projections. For the purposes of effects on water supply and wastewater treatment infrastructure, changes proposed by the project are relevant only if they would result in an ultimate increase in needed water production or wastewater treatment. Changes that do not adversely affect (increase or reallocate) populations or land uses within the unincorporated Riverside County area, are not discussed further here. For a summary of these areas and the rationale for their omission, see Section 4.17.1.

Water usage and wastewater generation rates estimate the amount of water needed and wastewater created by residences and businesses over a certain amount of time (day, year, etc.). For water use, all values are assumed to be for potable water, except for agriculture, parks and recreation. No SBX-7x7 required water conservation reductions were included in any of these calculations, even though in reality reductions of up to 20% by 2020 are to be pursued per this law (the Water Conservation Act of 2009). In regards to wastewater generation, it is assumed that all uses projected generate wastewater for sanitary sewer disposal in the typical ways. No diversion of graywater, process recycling, composting or other methods, in order to ensure a worst-case analysis. The water use and wastewater generation rates are intended to be used to estimate the impact of new developments on local water resources. In this way they are useful in providing a general level of information for planning purposes and estimating potential effects.

Table 4.19-BK provides a summary of the theoretical need for water supplies within Riverside County according to the theoretical estimate of need associated with existing land uses, as well as that for build out of the known spatial components or locations addressed by GPA No. 960 (i.e., site-specific LUD changes, policy area and study area changes, etc.). Likewise, Table 4.19-BL does the same for wastewater treatment facilities (as indicated by wastewater generation). Again, for the purposes of worst-case effects on facilities, the calculations assume 100% of the wastewater generated is collected by sanitary sewer systems and processed at wastewater treatment facilities. In reality, a certain amount of the wastewater generated would be disposed of via onsite waste treatment systems (particularly individual septic systems). This is discussed further below and, in particular, in Section 4.19.8 (Impacts and Mitigation).

It should also be noted that the following projections are based on the assumption that *all* of the changes proposed under GPA No. 960 actually result in future development and fully build out (as part of overall implementation of the Riverside County General Plan). That is, it is a theoretical, worst-case scenario that likely over-states the actual development potential in the real-world. The actual future development of the individual parcels and areas affected by GPA No. 960 proposals, as with build out of the rest of the General Plan, are subject to the discretion of many hundreds to thousands of individual property owners, including private individuals, business entities and even various public agencies and other entities.

For land use policy changes without currently assigned locations (Indian fee lands, incidental rural commercial, etc.), specific effects on water supply and wastewater generation/treatment cannot be delineated at present since they are land use-dependent. For the sake of comparison, however, Tables 4.19-BK and 4.19-BL show the theoretical water supply and wastewater treatment needs at build out for both the current General Plan and the General Plan as it would be if amended pursuant to proposed GPA No. 960.

Accordingly, Tables 4.19-BG and 4.19-BH show the water supply and wastewater treatment needs estimated to be generated for the existing (baseline) level of development currently present within the portions of Riverside County directly affected by proposed land use-related changes and for the land use of those same parcels of land as they would develop pursuant to the proposed project; in essence, with and without the proposed project. Because much of the area addressed by GPA No. 960 includes regions for which future development potential is being eliminated (e.g., deletion of Rural Village Study Areas), the first scenario (i.e., Tables 4.19-BG and 4.19-BH) includes many areas where the build out scenario under the updated General Plan is the same as that which would occur under the existing (current General Plan's) mapped LUDs. As such, these areas do *not* represent new areas of growth attributable to the project, GPA No. 960, but rather simply reflect the anticipated build out of the Riverside County General Plan that would occur with or without the project.

Table 4.19-BI: Theoretical Water Supply for Existing and Build Out Conditions

Land Use[1]	Generation Factors	Theoretical Water Supply (AFY)		
		Existing Uses of Land[2]	General Plan Build Out With GPA No. 960[3]	Difference
Residential	1.01 AFY per dwelling unit	5,850 du	16,570 du	+ 10,720 du
		5,910 AFY	**16,740 AFY**	**+ 10,830 AFY**
Commercial[4]	3.50 AFY per acre	70 acres	450 acres	+ 370 acres
		260 AFY	**1,560 AFY**	**+ 1,300 AFY**
Industrial[5]	0.97 AFY per acre	230 acres	280 acres	+ 50 acres
		230 AFY	**280 AFY**	**+ 50 AFY**
Total Area	**111,440 acres**	***6,400 AFY***	***18,570 AFY***	***+ 12,180 AFY***

Footnotes:
1. All results rounded after analysis to the nearest 10.
2. Theoretical need attributed solely to the portion of Riverside County associated with the lands proposed for spatial changes as part of GPA No. 960. See Section 4.1 for more details on how projections were derived.
3. Theoretical need associated with build out of the General Plan (including as updated pursuant to GPA No. 960) for the same spatial areas.
4. Includes the following land uses: commercial-retail (40%), commercial-tourist, commercial-office and business park.
5. Includes the following land uses: light industrial, heavy industrial and mineral resources.

Table 4.19-BJ: Theoretical Wastewater Generated by Existing and Build Out Conditions

Land Use[1]	Generation Factors[6]	Theoretical Wastewater Generation (gpd)		Difference
		Existing Uses of Land[2]	General Plan Build Out With GPA No. 960[3]	
Residential	230 gpd per dwelling unit	5,850 du	16,570 du	+ 10,720 du
		1,346,200 gpd	**3,811,300 gpd**	**+ 2,465,100 gpd**
Commercial[4]	1,200 gpd per acre	70 acres	450 acres	+ 370 acres
		87,600 gpd	**534,000 gpd**	**+ 446,400 gpd**
Industrial[5]	1,500 gpd per acre	230 acres	280 acres	+ 50 acres
		351,000 gpd	**426,000 gpd**	**+ 75,000 gpd**
Total Area	**111,440 acres**	***1,784,800 gpd***	***4,771,300 gpd***	***+ 2,986,500 gpd***

Key: gpd = gallons per day

Footnotes:

1. All results rounded after analysis to the nearest 10, except values in gallons (gpd) rounded to nearest 100.
2. Theoretical need attributed solely to the portion of Riverside County associated with the lands proposed for spatial changes as part of GPA No. 960. See Section 4.1 for more details on how projections were derived.
3. Theoretical need associated with build out of the General Plan (as updated by GPA No. 960) for the same spatial areas.
4. Includes the following land uses: commercial-retail (40%), commercial-tourist, commercial-office and business park.
5. Includes the following land uses: light industrial, heavy industrial and mineral uses.
6. All factors from Vallecitos Water District Master Plan, except for residential, which is from EIR No. 441.

Source: Riverside County Planning Dept., Project application data, 2010. For generation factors: Riverside County, EIR No. 441, 2003, and Vallecitos Water District Master Plan, Table 6-1, November 2010.

Thus, in order to focus on the areas where the proposed project would actually result in *new* development potential (i.e., potential impacts), a second scenario was developed. As shown in Tables 4.19-BI and 4.19-BJ, this second scenario includes only those areas proposed for a change that would result in an increase in future development density or intensity. This also includes all parcels in which an LUD was changed (except those being assigned to OS-CH due to their acquisition for open space conservation pursuant to the WRC-MSHCP; these parcels would be removed from development potential).

Lastly, the set of third tables, Tables 4.19-BM and 4.19-BN, show a "plan-to-plan" comparison between the build out conditions of the General Plan as it currently exists and then as it would be if GPA No. 960 were approved and fully implemented for water and wastewater, respectively. These tables indicate the relative effects of the project on long-range planning, rather than environmental impacts *per se*, and are provided for informational purposes and to allow comparison between build out outcomes.

On a comparative plan-to-plan basis, as shown in Tables 4.19-BK and 4.19-BL, the proposed project would result in a net decrease of roughly 46,000 AFY of potable water demand at countywide build out of the General Plan as amended by GPA No. 960. It would also generate roughly 16 mgd less wastewater at build out. Accordingly, it can reasonably be projected that services related to the production and conveyance of potable water (i.e., pumping, purification, storage, etc.) would be similarly decreased in proportion to the overall growth accommodated by the changes of the proposed project. The same assumption would apply to services and infrastructure associated with wastewater, e.g., wastewater treatment plant capacity, sludge disposal, etc.

Table 4.19-BK: Theoretical Water Supply for Areas of New Development Potential

Land Use[1]	Generation Factors	Theoretical Water Supply (AFY)		Difference
		Existing Uses of Land[2]	General Plan Build Out With GPA No. 960[3]	
Residential	1.01 AFY per dwelling unit	2,060 du	6,350 du	+ 4,290 du
		2,080 AFY	**6,410 AFY**	**+ 4,330 AFY**
Commercial[4]	3.50 AFY per acre	30 acres	370 acres	+ 340 acres
		110 AFY	**1,300 AFY**	**+ 1,190 AFY**
Industrial[5]	0.97 AFY per acre	110 acres	250 acres	+ 130 acres
		110 AFY	**240 AFY**	**+ 130 AFY**
Total Area	**10,690 acres**	***2,300 AFY***	***7,950 AFY***	***+ 5,640 AFY***

Footnotes:
1. All results rounded after analysis to the nearest 10.
2. Theoretical estimates for the land uses associated with the 10,690-acre area of known spatial project changes that would increase development intensity or density, or change an LUD in the Community Development Foundation.
3. Theoretical need associated with build out of the General Plan (including GPA No. 960) for the same spatial areas.
4. Includes the following land uses: commercial-retail (40%), commercial-tourist, commercial-office and business park.
5. Includes the following land uses: light industrial, heavy industrial and mineral resource uses.

Table 4.19-BL: Theoretical Wastewater Generation by New Development Potential Areas

Land Use[1]	Generation Factors[6]	Theoretical Wastewater Generation (gpd)		Difference
		Existing Uses of Land[2]	General Plan Build Out With GPA No. 960[3]	
Residential	230 gpd per dwelling unit	2,060 du	6,350 du	+ 4,290 du
		474,300 gpd	**1,459,800 gpd**	**+ 985,600 gpd**
Commercial[4]	1,200 gpd per acre	30 acres	370 acres	+ 340 acres
		38,400 gpd	**445,200 gpd**	**+ 406,800 gpd**
Industrial[5]	1,500 gpd per acre	110 acres	250 acres	+ 130 acres
		168,000 gpd	**369,000 gpd**	**+ 201,000 gpd**
Total Area	**10,690 acres**	***680,700 gpd***	***2,274,000 gpd***	***+ 1,593,400 gpd***

Footnotes:
1. All results rounded after analysis to the nearest 10, except values in gallons (gpd) rounded to nearest 100.
2. Theoretical estimates for the land uses associated with the 10,690-acre area of known spatial project changes that would increase development intensity or density, or change an LUD in the Community Development Foundation.
3. Theoretical need associated with build out of the General Plan (including GPA No. 960) for the same spatial areas.
4. Includes the following land uses: commercial-retail (40%), commercial-tourist, commercial-office and business park.
5. Includes the following land uses: light industrial, heavy industrial and mineral resource uses.
6. All factors from Vallecitos Water District Master Plan, except for residential, which is from EIR No. 441.

Source: Riverside County Planning Dept., Project application data, 2010. For generation factors: Riverside County, EIR No. 441, 2003, and Vallecitos Water District Master Plan, Table 6-1, November 2010.

In terms of actual land use and changes to baseline conditions, future development accommodated by the proposed General Plan changes would increase the amount of potable water demand by about 12,000 AFY and wastewater generation by approximately 3 mgd, as shown in Tables 4.19-BG and 4.19-BH, respectively. The additional demand for water and wastewater treatment would be generated a numerous individual locations throughout Riverside County, however, not localized to any single water or sewer service area or groundwater basin. It would also increase in small increments across a roughly 50-year build out period. As such, impacts to any single provider, treatment facility or groundwater basin would be slight and much of this growth is already planned for in the existing General Plan and was analyzed under EIR No. 441, which was certified for the 2003 RCIP General Plan.

Table 4.19-BM: Comparison of Existing General Plan and Proposed Updated General Plan Theoretical Water Demands at County Build Out

Land Use	Current General Plan		General Plan as Amended by GPA No. 960		Difference in Demand (AFY)
	Build Out Total[1]	Water Demand[2]	Build Out Total	Water Demand[2]	
Residential	534,100 du	**539,500 AFY**	498,000 du	**503,000 AFY**	***- 36,500 AFY***
Commercial[3]	14,000 acres	**48,800 AFY**	12,500 acres	**43,600 AFY**	***- 5,200 AFY***

2. The theoretical total volume of wastewater estimated to be generated annually at build out.
3. Includes land uses: commercial-retail (40%), commercial-tourist, commercial-office and business park.
4. Includes the following land uses: light industrial, heavy industrial and mineral resources uses.
5. All factors from Vallecitos Water District Master Plan, except for residential, which is from EIR No. 441.

Source: Riverside County Planning Dept., Project application data, 2010. For generation factors: Riverside County, EIR No. 441, 2003, and Vallecitos Water District Master Plan, Table 6-1, November 2010.

As mentioned above, Tables 4.19-BI and 4.19-BJ isolate just the areas of growth associated with GPA No. 960 that would potentially be greater than that originally planned under the existing General Plan. This highlights the changes that differ from the background levels already planned for under the existing General Plan. Once these areas are removed, the resultant scenario indicates that the future new development potential arising from GPA No. 960 would result in the need for approximately 5,640 AFY of potable water and the generation of roughly 1.6 million gpd of solid wastewater per year (before any recycling or water conservation programs). Because effects on water and sewer districts, as well as individual plants and infrastructure, are dependent upon geography (location), the water and wastewater data were further broken down by Area Plan.

Potable Water: The analysis indicates that most of the additional potable water supply for the project's future development potential would be needed in western Riverside County, particularly within the Elsinore Area Plan (approximately 1,600 AFY), Lakeview/Nuevo Area Plan (900 AFY) and Mead Area Plan (600 AFY), as a result of the new Rural Village Land Use Overlays associated with Good Hope and Meadowbrook, plus the revisions to the Lake Elsinore Environs (Lakeland Village) Policy Area. Most of these areas fall within WMWD's wholesale service area; the Lakeland Village and Meadowbrook overlays fall within Elsinore Valley Municipal Water District (a member agency of WMWD). The Good Hope Rural Village Overlay (within the Mead Valley Area Plan) is located in EMWD's service area, as is the Northeast Business Park overlay (within the San Jacinto Valley Area Plan). The Aguanga and Anza Rural Village Overlay (RVO) Study Areas are both in areas of REMAP without an existing water purveyor; a prominent reason why the increased densities/intensities associated with RVOs are proposed for elimination under GPA No. 960.

Within eastern Riverside County, the Palo Verde Valley Area Plan (with approximately 1,000 AFY) is the largest source of new demand, followed by the Western Coachella Valley Area Plan (roughly 600 AFY). The increased density/intensity proposed surrounding the Blythe Municipal Airport, as a result of ALUP adjustments, would be met through private groundwater wells exclusively. There is no municipal water purveyor in the area, other than the City of Blythe which does not, however, serve the unincorporated airport region. The majority of future development potential proposed within the Coachella Valley (the Western and Eastern Coachella Valley Area Plans) are located within the existing CVWD service area. This includes the existing and proposed fish farm (AG) designations around the Salton Sea.

Three other Area Plans (San Jacinto Valley, Southwest and Temescal Canyon) would need lesser additional water supplies (160 AFY, 60 AFY and 70 AFY, respectively). The remaining Area Plans would need little to no additional potable water (less than 50 AFY for Harvest Valley/Winchester, Eastern Coachella Valley and

REMAP; 0-20 AFY for the rest). These areas typically have much less development potential proposed. As an example, SWAP includes 540 acres proposed as Open Space-Rural development, which specifies 20-acre minimum lot sizes for new residences.

Wastewater: This chapter's analyses indicate that most of the additional wastewater that would be generated by the project's future development potential also would be needed predominantly in western Riverside County, for the same reasons as additional potable water would be needed. In particular, the Elsinore Area Plan are would need additional treatment capacity (roughly 479,300 gpd). Sanitary sewer services for this area are provided by EVMWD and WMWD. Similarly, the Lakeview/Nuevo Area Plan, served by EMWD for wastewater treatment, would need additional treatment capacity of roughly 223,500 gpd at build out and Mead Valley Area Plan (served by EVMWD and WMWD) would need 171,900 gpd.

The San Jacinto Valley and Jurupa would each need roughly 36,000 gpd additional wastewater treatment capacity. The Temescal Canyon, Southwest and REMAP Area Plans would need lesser amounts of additional capacity (16,500 gpd, 14,300 gpd and 9,500 gpd, respectively). The TCAP and SWAP regions would be served primarily by EMWD. The REMAP wastewater would be generated in areas without municipal wastewater treatment facilities. These wastes would be discharged to groundwater via OWTS (assuming such disposal was found suitable based on geology, hydrology and other limiting factors). The remaining areas would generate minor amounts of wastewater.

Within eastern Riverside County, the Palo Verde Valley Area Plan (generating approximately 219,400 gpd) is the largest source of additional wastewater. This region is not served by an existing municipal sanitary sewer system; all discharge to groundwater via OWTS and eventually reenter the water table fed by the Colorado River (see discussion under "City of Blythe" earlier in this chapter). In the unincorporated region of Coachella Valley, wastewater generated by future project development would be treated by CVWD. WCVAP would see roughly 128,400 gpd of additional wastewater generated, but ECVAP would have a 24,200 gpd decrease in development potential-driven generation. Thus, the net effect would be an overall increase of roughly 104,000 gpd. The remaining areas of the desert would generate negligible amounts of wastewater.

Hydrology: Lastly, with hydrology, future development potential increases could result in effects to the acreages indicated in Tables 4.19-BO, 4.19-BP and 4.19-BQ. Where sites are located within areas covered by an existing County Master Drainage Plan or Area Drainage Plan, all stormwater and surface flow systems would be required to be constructed pursuant to the standards of that plan. The infrastructure provided is normally either constructed by the site's developer or an in-lieu fee is paid. The applicable Area Drainage Plans set the specific standards for fees and construction.

In general, in areas with existing storm drain systems, future development would be required to connect to such systems. Where none exist, future developments would be required to provide sufficient onsite and/or offsite drainage facilities to ensure that no net flow increases occur.

C. Legal Background on Water Supply Adequacy

As explained above in Section 4.19.2, the California courts have provided specific guidance with respect to the requirements of a water supply analysis that is undertaken for a long-range development project or other long-range land use planning decision such as a general plan update. Thus, it is in light of this specific guidance that the CEQA thresholds of significance for water supply issues must be evaluated for purposes of GPA No. 960. Indeed, the California Supreme Court has stated: "Requiring certainty when a long-term, large-scale development project is initially approved would likely be unworkable, as it would require water planning to far outpace land use planning. Examination of other state statutes specifically addressing the coordination of land use and water planning supports our conclusion [that] CEQA should not be understood to require assurances of certainty regarding long-term future water supplies at an early phase of planning…." (Vineyard Area Citizens for Responsible Growth v. City of Rancho Cordova, 2007, 40 Cal.4th 412, 432.)

Further, the Supreme Court has also stated: "To interpret CEQA itself as requiring such firm assurances of future water supplies at relatively early stages of the land use planning and approval process would put CEQA in tension with these more specific water planning statutes.…[T]o satisfy CEQA, an EIR for a specific plan need not demonstrate certainty regarding the project's future water supplies." (*Id.* at 432, 437-438; see also Watsonville Pilots Association v. City of Watsonville (2010) 183 Cal.App. 4th 1059, 1090-1094.)

To the extent these standards were applied to a specific plan in the Vineyard case, they certainly apply to the general plan stage of land use decision-making as proposed by GPA No. 960. Of particular relevance to the long-term water supply planning horizon analyzed in this EIR for purposes of GPA No. 960, the Court of Appeal recently held: "Some level of uncertainty is a permanent, inherent feature of modern water management. It arises from a wide range of scientific and legal regulatory factors that cannot be avoided. Water management is subject to the vagaries of climate, competing demands from agricultural, industrial and residential uses, environmental constraints and overlapping regulatory regimes at both the federal and state levels." (Sonoma County Water Coalition v. Sonoma County Water Agency, 2010, 189 Cal.App.4th 33, 46).

All of these factors must be taken into consideration when examining the water analyses and conclusions presented in this EIR since this project and its EIR encompasses a wide variety of proposed changes affecting thousands of acres across numerous jurisdictional (and hydrological) boundaries. As such, specific water assessments were not performed at this programmatic level nor are specific water supplies identified at this time (beyond that generally addressed by the UWMPs cited herein).

In the more recent case of Watsonville Pilots Association v. City of Watsonville (2010, 183 Cal.App. 4th 1059), the EIR for the Watsonville Vista 2030 General Plan was challenged on various grounds, including water supply. Quoting from the Vineyard decision, the Court of Appeal in Watsonville Pilots upheld the water supply analysis on various grounds and determined that, "The burden of identifying likely water sources for a project varies with the state of project approval involved; the necessary degree of confidence involved for approval of a conceptual plan is much lower than for issuance of building permits." The EIR in that case acknowledged that water supply for the general plan area would be provided from an already overdrafted groundwater basin. The court found that the EIR contained considerable information and discussion of how the overdraft may be addressed in the future and stated: "It is not necessary for an EIR for a general plan to establish a likely source of water. Such a conceptual EIR need only adequately address the reasonably foreseeable impacts of supplying water to the project, note any uncertainties that preclude the identification of future water sources and discuss the reasonably foreseeable alternatives and environmental impacts of those alternatives."

4.19.8 Water Resources – Impacts and Mitigation

A. Would the project result in water supplies insufficient or unavailable to serve the project from existing entitlements and resources, or result in the need for new or expanded entitlements?

Impact 4.19.A – Result in Insufficient Water Supply: Future development accommodated by the land use and policy changes proposed by the project, GPA No. 960, has the potential to result in demand for water supplies where such are insufficient or unavailable to serve the project from existing entitlements and resources, thus necessitating new or expanded entitlements in order to adequately serve future development, or result in development in locations in which water supply adequacy cannot be ascertained. Due to the unavailability of potable water in some areas, as well as the variability and unpredictability of supply adequacy in light of future growth, as well as environmental and regulatory constraints, adequate water supplies for all forecast future development cannot be assured. As a result, within certain areas of Riverside County where sufficient water supply is not available or cannot be assured into the future, impacts would be significant and unavoidable.

1. Analysis of Impact 4.19.A

As shown in Table 4.19-BO, future development accommodated by GPA No. 960 has the potential to occur within and affect 111,400 acres of unincorporated Riverside County, including approximately 18,800 acres within existing water district service area boundaries (affecting 15 existing water districts) and 92,600 acres outside of water districts. Within the three categories of spatial project components, the 'Potentially Affected' area, which has the greatest potential to affect water supplies (because it generally represents foreseeable areas of increasing development potential), totals 7,900 acres and (per Table 4.19-BK) is associated with a *theoretical* water demand increase of approximately 5,600 AFY above baseline conditions at project build out.

As described in Section 4.19.4 (E-I), some of the affected water districts have forecast future water demands in excess of the supply available. Where demand for water exceeds supply, a significant impact would occur. Unavailability or unpredictability of imported water supplies, overdraft of groundwater basins, increasing demand due to growth in Riverside County, as well as environmental factors, such as climate change effects and drought, all play roles in limiting the availability of water within Riverside County. In some remote locations, particularly in the far eastern desert beyond the Coachella Valley and the region south of the San Jacinto Mountains between Anza and Coachella Valley, lack of groundwater and/or lack of delivery infrastructure also are limiting factors. For all of these reasons, the impact of water supply insufficiency is deemed significant and unavoidable at this time.

In total, future development accommodated by the project would increase demand for water services to a degree that exceeds the limits of existing and currently planned facilities to provide. Water agencies generally operate on a 'will serve' capacity – building facilities and hiring staff based on demand projections for their service areas. Most of the larger water agencies plan their facilities using a 5-year horizon, usually in the form of a five-year capital improvements program that is updated annually. Because of this, any project that uses a planning horizon of more than five years is likely to exceed the limits of facilities planned by local water agencies. Such is the case with the proposed project, the build out of which spans a nearly 50-year period.

Options available to address future water shortfalls include both infrastructure projects (such as storage facilities and water reclamation plants) and water management strategies (such as conservation practices) that affect how water is used. Also, water districts urban water management plans only project water supply and demand out 25 years (currently to 2035). Thus, any assumptions for future water supplies beyond 2035 are also speculative.

The existing General Plan, as well as GPA No. 960, includes policies that establish and reiterate appropriate water management strategies at the county level, including conservation, collection of information, decreasing demand, outreach and education programs, assurances of adequate groundwater recharge areas and water supply monitoring. See discussion in Sections 4.19.5.D and E. No adverse impacts are anticipated from such strategies, as they would reduce overall water demand and, in some instances, supply additional sources of water for irrigation and other non-potable uses. Infrastructure projects are likely to be proposed both by the County of Riverside and by water suppliers. The construction of additional water storage facilities, as well as water reclamation plants, would be subject to additional environmental analysis to determine the project's specific impacts. Conservation and recycled water sources would not further deplete groundwater supplies or increase reliance on imported water.

Securing additional imported water is another way to increase the water supply. Such water could come from existing imported sources (i.e., the Colorado River or other State Water Project sources), or could come from yet-to-be negotiated sources. The impacts of drawing water from sources outside the region would require further analysis if such proposals were undertaken. They could include impacts to biological resources (i.e., from decreased water flow in rivers), impacts to other jurisdictions that rely on that water source (e.g., as water supply or for groundwater recharge), growth-inducing impacts and other environmental and economic impacts.

Nevertheless, in the absence of a definitive identification of future water supply, potential impacts associated with water supply and demand must be considered significant and unavoidable.

2. Regulatory Compliance Affecting Impact 4.19.A

The adverse effects associated with potential demands on existing water resources, or need for new entitlements, would be avoided, reduced or minimized through adherence to and compliance with the following regulations, policies and existing mitigation measures.

a. Compliance with Federal and State Regulations

Compliance with the following state and federal regulations would help reduce impacts due to insufficient water supplies.

Federal Water Pollution Control Act of 1972 (aka the Clean Water Act): As described further under Impact 4.19.C, this far-reaching collection of regulations address a variety of water resource issues. The regulations encompassed in the Clean Water Act provide strong water quality protection, including protecting watersheds from runoff and erosion pollution, polluting discharges and hydrological disruptions. These protections ensure that the water quality of is protected and that surface and groundwater sources remain safe and suitable for use as drinking water, irrigation water, recharge water and other beneficial uses.

Federal Safe Drinking Water Act: Compliance with the EPA's minimum standards set under this act serves to protect tap water from potentially harmful contaminants and regulates pollutants that could affect groundwater basins, in particular 'sole source aquifers.' It also protects public health by limiting the levels of contaminants in drinking water. Thus, compliance with this act helps protect water quality and viability of existing and future drinking water supplies.

California Porter-Cologne Water Quality Control Act of 1970: As described more fully under Impact 4.19.C, compliance with the various regulations and programs of this act serves to protect surface and groundwater sources from pollutant discharges, runoff and erosion, unpermitted hydrology disturbances and other activities

that would adversely affect surface or groundwater. Together these measures protect water quality and ensure that surface and groundwater sources remain safe and suitable for use as drinking water, irrigation water, recharge water and other beneficial uses.

California Safe Drinking Water Act: As described further under Impact 4.19.C, this act protects water quality, particularly for groundwater drinking supplies. Thus compliance with this act helps ensure water supplies of suitable water quality are available when needed for public consumption.

CCR Title 22 - Recycled Water: Chapter 4 of CCR Title 22 establishes recycled water quality standards and treatment reliability criteria dependent upon the end use of recycled water to protect public health. Both secondary- and tertiary-treated wastewater can meet Title 22 standards, dependent upon the end use of the water. Utilization of recycled water for groundwater recharge is reviewed by DHS on a case-by-case basis. Processing of recycled water in compliance with these standards would ensure that additional water supply is made available and that the available water meets all applicable state and federal water quality standards. Increased water conservation and use of recycled water would also help reduce reliance on imported water supplies and lessen draw-down of groundwater, aiding water districts in ensuring adequate water supply availability.

Water Conservation Act (SBX 7-7): This law requires that the State of California reduce urban per-capita water use statewide by 10% by the end of 2015 and 20% by the end of 2020. In addition, agricultural water suppliers must adopt agricultural water management plans by the end of 2012 and then update their plans by the end of 2015 and every five years thereafter. Compliance with this act would help reduce the amount of water consumed by various users, including new urban development. The result would be to make additional water (potentially up to 20%) available for use. Increased water conservation would also help reduce reliance on imported water supplies and lessen draw-down of groundwater. This would also help increase the available water supply needed to serve Riverside County.

Senate Bill 610: As explained in Section 4.19.5, all future implementing projects of a certain size or character are required to prepare a water supply assessment (WSA). This generally includes those having a water demand equivalent to a project with 500 dwelling units or more, but also includes a variety of other specific projects as defined by the WSA statute (see CWC Section 10912(a)). Generally, a WSA must include an analysis of whether the total projected water supplies available to the water provider during normal, single-dry and multiple-dry years over the next 20-year period are sufficient to meet the projected water demand associated with the project, in addition to existing and planned future uses. Additional analysis is required if the water supplies identified to serve the project include groundwater. The WSA statute provides additional means for the County of Riverside and cities to evaluate water supply sufficiency for certain specific projects that may be proposed pursuant to GPA No. 960.

Senate Bill 221: Similar to the requirements of SB 610, CGC Sections 65867.5 and 66473.7, generally require the County of Riverside and cities to include as a condition of approval for any tentative tract map or development agreement that includes a subdivision (defined as a residential development containing 500 or more dwelling units) a requirement that a sufficient water supply is or will be available to serve the subdivision. The availability of a sufficient water supply must be based on written verification from the public water system that will provide the water service. As with the standard provided by SB 610, a "sufficient water supply" under SB 221 is the total water supplies available to the water provider during normal, single-dry and multiple-dry years within a 20-year projection that will meet the projected demand of the proposed subdivision, in addition to existing and planned future uses, including agricultural and industrial. The water provider's verification must be based on substantial evidence, such as water supply contracts, capital outlay programs and regulatory permits and approvals regarding the water provider's right to and capability of delivering the necessary project supply. Compliance with this law would help minimize impacts to water supplies by providing a basis upon which the County of Riverside and

cities could determine not to approve certain residential development projects if sufficient water supplies are not available to serve them.

b. Compliance with Existing Riverside County Regulations

Compliance with the following Riverside County regulations would prevent or reduce significant impacts to water supplies. These regulations are already in effect in Riverside County and are not part of the project, GPA No. 960. Rather, these policies are considered to play a role in ensuring any potential environmental effects are avoided, reduced or minimized through their application on a case-by-case basis. The County of Riverside has existing programs in place that ensure applicable policies are imposed once a development proposal triggers a specific policy or policies. The need for specific policies is determined through subsequent site-specific CEQA analysis performed at the time of implementing project review. These measures are implemented, enforced and verified through their inclusion into project conditions of approval.

Ordinance No. 458 - Regulating Flood Hazard Areas and Implementing the National Flood Insurance Program: Among other things, this ordinance includes measures to ensure water and wastewater systems are adequately protected from flooding and would not contaminate or be contaminated by floodwaters. Thus, Ordinance No. 458 serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater. See Impact 4.19.D for more information.

Ordinance No. 592 – Regulating Sewer Use, Sewer Construction and Industrial Wastewater Discharges in County Service Areas: This ordinance sets various standards for sewer use, construction and industrial wastewater discharges within Riverside County to protect both water quality and the infrastructure conveying and treating these wastewaters. As a result, Ordinance No. 592 serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 617– Hazardous Substances (Regulating Underground Storage Tanks): This ordinance prevents long-term threats to the public health, water quality and local water supplies (surface and groundwater) from underground tank systems.

Ordinance No. 650 – Sewer Discharge in Unincorporated Territory: This ordinance protects water quality, storm drains and surface waters by prohibiting the discharge or deposition of any sewage, sewage effluent or non-hazardous waste, treated or untreated, into any streams or bodies of water above or below the ground, within Riverside County. Thus, Ordinance No. 650 protects water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 682 – Construction, Reconstruction, Abandonment and Destruction of Wells: This ordinance establishes minimum standards for wells to protect underground water resources and provide safe water within Riverside County by requiring county permits for these activities. As a result, Ordinance No. 682 protects water supplies, as well as water quality, for groundwater.

Ordinance No. 856 – Establishing a Septic Tank Prohibition for Specified Areas of Quail Valley and Requiring the Connection of Existing Septic Systems to Sewer: This ordinance protects groundwater water quality in the Quail Valley region of Riverside County by prohibiting new septic systems and modifications to existing systems. This improves water supplies, water and wastewater facilities and water quality for both surface water and groundwater in the Quail Valley region, as well as Canyon Lake (impaired due to sewage runoff) and the water users relying on it as a supply source.

Ordinance No. 859 – Water-Efficient Landscape Requirements: By requiring a reduction in the amount of water used for landscape irrigation, Ordinance No. 859 protects existing water supplies (surface and groundwater). And by limiting water applications, it also helps minimize water runoff and water erosion in landscaped areas.

Ordinance No. 871 – Prohibiting the Installation of Specified Septic Tank Systems in Cherry Valley: This ordinance was enacted to protect water quality in the Cherry Valley region of Riverside County from high nitrate levels in drinking water as a result of failing septic systems. As a result, this ordinance serves to protect water supplies and groundwater quality in the region. It does so by prohibiting additional septic systems.

c. Compliance with Existing General Plan Policies

Implementation of the following water resource-related General Plan policies would help reduce the effects of future development on water supply, but would not fully reduce the significant impact associated with supply insufficiency or the need for new water entitlements. See Section 4.19.5.D for full text of each of these policies.

Policies OS 1.1 and 1.3: These policies address water supply issues at the county level and when considering projects for approval.

Policies OS 2.2 and 2.5: These policies address water conservation by encouraging the use of recycled water. Increased use of recycled water and water conservation reduces the need for imported water supplies and decreases draw-down of local groundwater basins.

Policies LU 5.3, 21.2, 28.3, 29.7, 30.7, 31.4 and 32.6: These policies address project consistency with urban water management plans and require projects be reviewed to ensure water resources are adequate for the proposed level of development.

d. Compliance with Proposed New or Revised General Plan Policies

The following proposed new or revised policies of the Riverside County General Plan would address potential impacts to water resources and supplies. See Section 4.19.5.D for full text of each of these.

Policies OS 1.4, 2.3 and 2.4: These policies address water conservation by encouraging the use of recycled water. Increased use of recycled water and water conservation reduces the need for imported water supplies and decreases draw-down of local groundwater basins.

New Policies OS 2.1 and 18.1-18.6: These policies address water conservation through requirements for water-efficient landscaping. Decreasing irrigation water use means reducing the need for imported water supplies and decreasing draw-down of local groundwater basins.

New Policy LU 22.2: This policy ensures water resources are adequate for the proposed level of development.

e. Compliance with Mitigation Measures from EIR No. 441

These specific mitigation measures from EIR No. 441 address water supplies directly: existing Mitigation Measures 4.17.2A and 4.17.3A (described in nder Impact 4.19.B), would also aid in reducing impacts to water supplies.

Existing Mitigation Measure 4.17.1C: Development within unincorporated areas of the County [of Riverside] shall not use water of any source of quality suitable for potable domestic use for non-potable uses, including cemeteries, golf courses, parks, highway landscaped areas, industrial and irrigation uses, or other non-domestic use if suitable recycled water is available as provided in Sections 13550-13566 of the [California] Water Code and/or Sections 65591-65600 and 65601-65607 of the Public Resource Code. Prior to the issuance of any land use permit, the County [of Riverside] shall determine to what extent and in which manner the use of recycled water is required for individual water projects. Future development shall be designed, constructed and maintained in accordance with the recycled water measures mandated by the County [of Riverside].

Existing Mitigation Measure 4.17.1D: Riverside County shall enforce compliance with federal, state and local standards for water conservation within residential, commercial or industrial projects. Prior to approval of any development within the County [of Riverside], the applicant shall submit evidence to Riverside County that all applicable water conservation measures have been met.

Existing Mitigation Measure 4.17.1E: For any development within the [DWR-designated] Palo Verde Planning Area supplied with water from the Colorado River, the project applicant shall enter into a contract with the City of Needles [the LCWSP water contractor], pursuant to the Lower Colorado Water Supply Project program. Evidence of such a contractual agreement shall be submitted to the County [of Riverside] prior to the approval of any development entitlement for the project.

3. Finding on Significance for Impact 4.19.A

Implementation of the above regulations, General Plan policies and existing EIR No. 441 mitigation measures would reduce or minimize potential impacts to water supply associated with future development accommodated by GPA No. 960. However, they do not fully mitigate potential significant impacts that would arise from project-driven future increases in demand for and use of water. Nor do they provide the means to ensure water supplies are secured for the proposed areas. Thus, even with the above measures, impacts to water supply would remain significant and unavoidable.

B. Would the project substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted)?

Impact 4.19.B – Substantially Deplete Groundwater Supplies or Interfere Substantially with Groundwater Recharge: Future development accommodated by the land use and policy changes proposed by the project, GPA No. 960, would increase population within Riverside County, triggering increased water demands on areas relying on groundwater supplies. This is particularly likely in areas of Riverside County without municipal water service or other access to imported water supplies or where new development would rely solely on groundwater for supply. Increased and new uses may also conflict with groundwater management plans, monitoring programs or lead to groundwater extractions that individually or cumulatively exceed the groundwater basins' safe yields or cause a net deficit in the aquifer volume or reduction in the local water table level. In addition, there is the potential for future development accommodated by the project to occur in vacant areas that are currently available for groundwater recharge. Development of such areas would reduce the area available for aquifer recharge and could substantially interfere with the process of groundwater recharge. A number of regulatory policies and

programs address groundwater impacts. However, where groundwater recharge is insufficient, such increased demand on aquifers would result in significant and unavoidable impacts.

1. Analysis of Impact 4.19.B

Groundwater levels in many areas of Riverside County were once much higher than they are today. As groundwater has been and continues to be extracted at a faster rate than it is replenished, the problems associated with overdraft and the lowering of the groundwater table are likely to continue. In the search for new water supplies, groundwater of marginal quality, high in salts or organic compounds, may be extracted and treated to meet drinking water standards and distributed for domestic and municipal uses. This action risks the overuse and overdraft of groundwater in basins with little history of extensive extraction. Increasing demands and costs, as well as unpredictability in the availability of imported water would make it more attractive for water suppliers to exploit the local, and sometimes marginal quality, groundwater supplies.

Several areas of Riverside County have basins where water rights, including amounts of groundwater extraction, have been determined by adjudication. Adjudication ensures a level of consistency and certainty that can be used in long-term water supply planning for each agency and/or party named in the judgment. Without an area-wide groundwater management and monitoring program, there is little surety of long-term supply. When a single agency has the power and responsibility to manage the groundwater resources of an area, it can change its management strategy at any time. Because of this, there continues to be a risk of overdraft in the non-adjudicated groundwater basins in Riverside County as demand for water increases. In adjudicated basins, however, where extraction limits are met, additional water needs beyond those limits would have to be met by importing water from elsewhere, increasing conservation and also reclaiming or recycling water.

The combination of increased demand for water associated with the growth envisioned by the project, unpredictability and the cost of imported water supply, variability in long-term supply scenarios in non-adjudicated basins, exploitation of new groundwater sources and the continuing pattern of basin overdraft, would all result in or contribute incrementally to substantially decreasing groundwater supplies. In addition, an assessment of future water supply adequacy beyond the year 2035 (including groundwater) is speculative. Since at present roughly one-third of Riverside County's water demand is met by groundwater, this unpredictability and variability mean that significant impacts associated with project build out over the next 50-plus years cannot be ruled out.

The water that recharges aquifers (groundwater basins) comes from precipitation, excess irrigation, incidental percolation from reclaimed water ponds and recharge of off-season imported water in recharge ponds managed by water agencies. The majority of groundwater recharge comes from precipitation. Efficient recharge from precipitation depends on a variety of conditions including large areas of permeable surfaces free from oil and grease, and relatively slow flow of water across that surface so infiltration of water into groundwater basins can occur.

Increased development reduces the amount of permeable surfaces suitable for recharge, increases runoff and the subsequent flow of water in streams, and increases the amount of oil and grease and other non-point source pollutants that enter streambeds and other recharge areas. Groundwater resources in Riverside County are defined by their quality as well as quantity. Most groundwater basins within Riverside County store local and imported water to meet seasonal and drought-year demand. With a typical groundwater recharge program, groundwater is artificially replenished in wet years with surplus imported water. Water is withdrawn from groundwater reserves during periods of drought or during emergency situations. Groundwater recharge programs may utilize reclaimed water during recharge activities. Groundwater recharge programs enhance a region's ability to meet water demand during years of short supply and increase the reliability of local water supplies. Thus,

increased development of buildings, parking lots, roads, roofs and other impervious surfaces could also directly affect groundwater levels by decreasing water infiltration and groundwater recharge rates.

2. Regulatory Compliance Affecting Impact 4.19.B

The adverse effects associated with potential demands on groundwater and effects on groundwater recharge would be avoided, reduced or minimized through adherence to and compliance with the following regulations, policies and existing mitigation measures.

a. Compliance with Federal and State Regulations

Compliance with the following state and federal regulations would help reduce groundwater impacts.

Federal Water Pollution Control Act of 1972 (aka the Clean Water Act): As described under Impact 4.19.C below, the regulations encompassed in the Clean Water Act ensure that surface and groundwater sources remain safe and suitable for use as drinking water, irrigation water, recharge water and other beneficial uses.

Federal Safe Drinking Water Act: Compliance with this act helps protect water quality and viability of existing and future drinking water supplies, including those from groundwater sources.

California Porter-Cologne Water Quality Control Act of 1970: As described under Impact 4.19.C, compliance with this act protects surface and groundwater sources from pollutant discharges, runoff and erosion, unpermitted hydrology disturbance and other activities that would adversely affect surface or groundwater. These programs protect water quality and ensure that surface and groundwater sources remain safe and suitable for use as drinking water, irrigation water, recharge water and other beneficial uses.

CCR Title 22 - Recycled Water: These recycled water standards would help ensure additional water supply availability. Increased water conservation and use of recycled water would help reduce reliance on imported water supplies and lessen draw-down of groundwater.

Water Conservation Act (SBX 7-7): Compliance with this act would help reduce the amount of water consumed by various users, including new urban development, and would thus make additional water (potentially up to 20%) available for use. Increased water conservation would also help reduce reliance on imported water supplies and lessen draw-down of groundwater.

Senate Bill 610: As explained in Section 4.19.5, all future implementing projects of a certain size or character are required to prepare a water supply assessment (WSA). The WSA statute provides an additional means for the County of Riverside and cities to evaluate water supply sufficiency for certain specific projects that may be proposed pursuant to GPA No. 960.

Senate Bill 221: As explained in Section 4.19.5, compliance with this law would minimize impacts to water supplies by providing a basis upon which the County of Riverside and cities could determine not to approve certain residential development projects if sufficient water supplies are not available to serve them.

b. Compliance with Existing Riverside County Regulations

Compliance with these regulations would prevent or reduce significant impacts to groundwater. These regulations are already in effect in Riverside County and are not part of the project, GPA No. 960. Rather, these

policies are considered to play a role in ensuring any potential environmental effects are avoided, reduced or minimized through their application on a case-by-case basis. The County of Riverside has existing programs in place that ensure applicable policies are imposed once a development proposal triggers a specific policy or policies. The need for specific policies is determined through subsequent site-specific CEQA analysis performed at the time of implementing project review. These measures are implemented, enforced and verified through their inclusion into project conditions of approval.

Ordinance No. 682 – Construction, Reconstruction, Abandonment and Destruction of Wells: This ordinance establishes minimum standards for construction, reconstruction, abandonment and destruction of wells in order to protect underground water resources and provide safe water within Riverside County by requiring county permits for these activities. It also sets standards for these activities pursuant to those "recommended in the Bulletins of the California Department of Water Resources" and contains prohibitions on placing wells where sources of pollution or contamination could contaminate or pollute the well water. The ordinance also sets a variety of water quality standards for water supply wells pursuant to the standards for constituents required in the California Code of Regulations, Title 22, "Domestic Water Quality and Monitoring," and requires testing of all individual domestic water wells to assess water quality compliance. Through these means, Ordinance No. 682 protects water supplies, as well as water quality, for groundwater.

Ordinance No. 856 – Establishing a Septic Tank Prohibition for Specified Areas of Quail Valley and Requiring the Connection of Existing Septic Systems to Sewer: This ordinance was enacted to protect the water quality of groundwater in the Quail Valley region of Riverside County by prohibiting both new septic systems and modifications to existing systems. The prohibitions and restrictions of Ordinance No. 856 serve to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater in the Quail Valley region, and Canyon Lake (a designated 'impaired waterbody' due to sewage runoff). It also protects the health of water users relying on it as a water supply source.

Ordinance No. 871 – Prohibiting the Installation of Specified Septic Tank Systems in Cherry Valley: This ordinance was enacted to protect water quality in the Cherry Valley region of Riverside County from high nitrate levels in drinking water as a result of failing septic systems by prohibiting new septic systems and expansions or modifications of existing septic systems within the region. It serves to protect water supplies and groundwater quality in the region. It does so by prohibiting additional septic systems.

c. Compliance with Existing General Plan Policies

Implementation of the following water resource-related General Plan policies would help reduce the effects of future development on groundwater, but would not fully reduce significant impacts associated with increasing use of groundwater. See Section 4.19.5.D for full text of each of these policies.

Policies OS 1.1 and 1.3: These policies address water supply issues at the county level and when considering projects for approval.

Policies OS 2.2 and 2.5: These policies address water conservation by encouraging the use of recycled water. Increased use of recycled water and water conservation reduces the need for imported water supplies and decreases draw-down of local groundwater basins.

Policies OS 4.1-4.3: These policies address programs to support aquifer recharge which is necessary to prevent excessive draw-down of groundwater basins.

Policies OS 4.4 and 4.8: These policies address protection of natural drainages which contribute to aquifer recharge and aid in protecting groundwater basins from draw-down.

Policies LU 5.3, 21.2, 28.3, 29.7, 30.7, 31.4 and 32.6: These policies address project consistency with urban water management plans and require projects be reviewed to ensure water resources are adequate for the proposed level of development.

d. Compliance with Proposed New or Revised General Plan Policies

The following proposed new or revised policies of the Riverside County General Plan would address potential impacts to water resources. See Section 4.19.5.D for full text of each of these policies.

Policies OS 1.4, 2.3 and 2.4: These policies address water conservation by encouraging the use of recycled water. Increased use of recycled water and water conservation reduces the need for imported water supplies and decreases draw-down of local groundwater basins.

Policies OS 4.5 and 4.6: These policies address protection of natural drainages which contribute to aquifer recharge and aid in protecting groundwater basins from draw-down. In particular, policy OS 4.6 addresses the retention of stormwater runoff within a development site in order to both prevent erosion offsite and facilitate groundwater recharge onsite.

New Policies OS 2.1 and 18.1-18.6: These policies address water conservation through requirements for water-efficient landscaping. Decreasing irrigation water use means reducing the need for imported water supplies and decreasing draw-down of local groundwater basins.

New Policies OS 3.4-3.7: These policies address requirements to comply with NPDES and other regulations addressing pollution discharges and runoff to protect stormwater quality and, ultimately, surface and groundwater fed by stormwater runoff.

New Policy LU 22.2: This policy ensures water resources are adequate for the proposed level of development.

e. Compliance with Mitigation Measures from EIR No. 441

In addition to the above, several specific mitigation measures from EIR No. 441 address groundwater supplies and recharge. Existing Mitigation Measures 4.17.1C, 4.17.1D and 4.17.1E, listed under Impact 4.19.A, would also aid in reducing impacts to groundwater supplies.

Existing Mitigation Measure 4.17.2A: In areas where it is not practical to conserve soils suitable for recharge (as determined by the Riverside County Flood Control and Water Conservation District), water harvesting and recharge facilities shall be built within the same groundwater basin in which the recharge area is lost. The construction of 'replacement' recharge areas shall equal the amount of recharge area lost and/or shall incorporate equipment or facilities capable of replacing (at an equal volume) the amount of groundwater recharge capacity lost as a result of development. The identification, designation, location or installation of 'replacement' groundwater recharge capacity shall be reviewed and approved by the Riverside County Flood Control and Water Conservation District prior to the issuance of grading permits.

Existing Mitigation Measure 4.17.3A: New development that includes more than one acre of impervious surface area (including roofs, parking areas, streets, sidewalk, etc.) shall incorporate features to facilitate the onsite

infiltration of precipitation and/or runoff into groundwater basins. Such features shall include (but not be limited to): natural drainage systems (where economically feasible), detention basins incorporated into project landscaping; and the installation of porous areas within parking areas. Where natural drainage systems are utilized for groundwater recharge, they shall be managed using natural approaches (as modified to safeguard public health and safety). Groundwater recharge features shall be included on development plans and shall be reviewed by the Riverside County Building and Safety Department and/or Riverside County Flood Control and Water Conservation District prior to the issuance of grading permits.

3. Finding on Significance for Impact 4.19.B

While the above regulations, ordinances, General Plan policies and existing mitigation measures from EIR No. 441 would reduce or minimize potential impacts to groundwater usage and its recharge as a result of future development accommodated by GPA No. 960, they do not address specific groundwater basin usage or the site-specific groundwater recharge impacts that would result indirectly from implementation of the proposed project. In some cases, such onsite recharge mitigation may be infeasible for insufficient to offset the impact to groundwater. In addition, agency data demonstrating groundwater supply and demand into the future only extends to 2035, thus making supply assumptions for this project to full build out (approximately 2060) tenuous at best. Thus, even with the above measures, impacts to groundwater and groundwater recharge would remain significant and unavoidable.

C. Would the project substantially degrade water quality?

Impact 4.19.C – Substantially Degrade Water Quality: Future development accommodated by the land use and policy changes proposed by the project, GPA No. 960, would result in an increased reliance on lower-quality water sources either from the Colorado River or marginal groundwater sources and would contribute to increased levels of pollutants in local/regional groundwater reserves and local/regional surface waters. These conditions would contribute to the deterioration of the quality of drinking water in Riverside County. Compliance with existing laws, regulatory programs, ordinances, General Plan policies and existing mitigation measures from EIR No. 441, however, would be sufficient to ensure that this impact is less than significant.

1. Analysis of Impact 4.19.C:

Water quality problems in Riverside County have occurred due to inadequate subsurface sewage disposal and waste disposal management of the Santa Ana River watershed, agricultural operations (e.g., agricultural runoff), the buildup of sediment resulting from construction-related erosion, and urban stormwater runoff. The State of California's Regional Water Quality Control Boards (RWQCBs) provide water quality policy guidance for Riverside County (e.g., via NPDES general permits and MS4 permits). In particular, the NPDES permit process mandates the use of BMPs to minimize the adverse effects of pollution and to protect water quality.

Future development accommodated by the project would result in increased population in Riverside County. This increase in population would increase the amount of wastewater generated, decrease the quality of treated wastewater (where wastewater is not fully processed) and increase the need for effluent disposal. The effluent, when discharged into a stream, or other surface water body, has the potential to degrade the quality of the water in the receiving water body. Additionally, stormwater runoff from urban areas contains a variety of organic and inorganic substances that may reduce the quality of groundwater when introduced into their aquifers. Non-consumptive beneficial water uses, such as contact and non-contact recreation, warm and cold water habitat, and habitat for sensitive plant/animal species, may also be affected by degradation of water quality resulting from the future development.

Currently, Riverside County relies on imported water and local groundwater for its municipal water supplies. Desalted groundwater is also being pursued as a supply option in the western Riverside County. The amount of water required for agricultural uses could be reduced by improving the efficiency of irrigation procedures and/or by implementing various water conservation practices in agricultural operations. If the amount of water required for agricultural uses is reduced, it is anticipated that more water (e.g., from the Colorado River) would be available for urban use. However, Colorado River water is generally of lower quality than water supplies from Northern California. In addition, during periods when water supply availability has been reduced (e.g., during droughts), an increase in the withdrawal of water from wells previously shut down because of contamination may also occur. To maintain acceptable water quality, water from these sources must be blended with water from non-contaminated sources. While water supplies resulting from this 'blending' process must continue to meet all water quality standards, it would generally be of lower overall quality than water supplied solely from non-contaminated sources. The increased usage of water from the Colorado River and blended water would result in general deterioration of water quality in Riverside County.

2. Regulatory Compliance Affecting Impact 4.19.C

The adverse water quality effects associated with future development accommodated by the project would be avoided, reduced or minimized through adherence to and compliance with the following regulations, policies and existing mitigation measures.

a. Compliance with Federal and State Regulations

Compliance with the following regulations would help reduce impacts due to water quality.

Federal Water Pollution Control Act of 1972 (aka the Clean Water Act): This far-reaching collection of laws address a variety of water resource issues. It contains regulatory provisions that impose progressively more stringent requirements on industries and cities to reduce pollution and meet the goal of zero discharge of pollutants. In particular, compliance with the Clean Water Act's Section 303 standards and requirements, protects existing water quality and establishes programs to restore waterbodies with impaired water quality. Compliance with Section 401 requires activities and facilities that would discharge pollutants into waters of the U.S. to obtain a State of California water quality certification proving that the activity complies with all applicable water quality standards, limitations and restrictions. Lastly, compliance with Section 404 of the act is designed to ensure that the chemical, physical and biological functions of the waters are protected. It includes mandatory measures to avoid, minimize and mitigate impacts. Together, these regulations provide strong water quality protection, including protecting watersheds from runoff and erosion pollution, polluting discharges and hydrological disruptions. These protections ensure that surface and groundwater sources remain safe and suitable for use as drinking water, irrigation water, recharge water and other beneficial uses.

Federal Safe Drinking Water Act: Compliance with the EPA's minimum standards set under this act serves to protect tap water from potentially harmful contaminants. This act regulates pollutants that could affect groundwater basins, in particular 'sole source aquifers.' All owners or operators of public water systems must comply with these primary standards, which protect public health by limiting the levels of contaminants acceptable in drinking water. Compliance with this act helps protect water quality and the viability of existing and future drinking water supplies.

California Porter-Cologne Water Quality Control Act of 1970: Administered by the State Water Resources Control Board and the Regional Water Quality Control Boards, this act regulates water pollution within California by protecting water quality and beneficial uses of all state waters. It implements the CWA at the state level

through the adoption of various plans and policies, the regulation of discharges and waste disposal sites, and the cleanup of hazardous materials and other pollutants. In particular, it is the basis for the State of California's enforcement and administration of the NPDES program at the local level. Compliance with the rules, regulations, policies and programs promulgated by the State of California pursuant to this act serves to protect surface and groundwater sources from pollutant discharges, runoff and erosion, unpermitted hydrology disturbance and other activities that would adversely affect surface and groundwater. Together, these protections protect water quality and ensure that surface and groundwater sources remain safe and suitable for drinking, irrigation, groundwater recharge and other beneficial uses.

California Safe Drinking Water Act: In addition to the federal Safe Drinking Water Act, drinking water quality is also regulated under the State of California's Safe Drinking Water Act (California Health and Safety Code Section 116270, *et seq.*) and associated regulations. Compliance with the National Primary Drinking Water Regulations (NPDWRs) or the more stringent state-established maximum contaminant levels (MCLs) ensures that contaminants that affect health achieve (as close as economically and technically feasible) the applicable 'public health goal.' This is the drinking water contaminant level below which there is no known or expected risk to health, as set by the California Office of Environmental Health Hazard Assessment. Secondary MCLs are also set to protect the odor, taste and appearance of drinking water. By protecting water quality, compliance with this act would help ensure water supplies of suitable quality are available for public consumption.

CCR Title 22 - Recycled Water: Recycled water made available in compliance with these regulations would help reduce reliance on imported water supplies and lessen draw-down of groundwater.

b. Compliance with Existing Riverside County Regulations

Compliance with the following Riverside County regulations would prevent or reduce significant impacts to water quality. These regulations are already in effect in Riverside County and are not part of the project, GPA No. 960. Rather, these policies are considered to play a role in ensuring any potential environmental effects are avoided, reduced or minimized through their application on a case-by-case basis. The County of Riverside has existing programs in place that ensure applicable policies are imposed once a development proposal triggers a specific policy or policies. The need for specific policies is determined through subsequent site-specific CEQA analysis performed at the time of implementing project review. These measures are implemented, enforced and verified through inclusion in project conditions of approval.

Ordinance No. 427 – Regulating the Land Application of Manure: This ordinance generally regulates the transportation and application of manure in designated areas of Riverside County. Compliance with Ordinance No. 427 helps protect water quality for runoff, surface and groundwater.

Ordinance No. 457 - Building Codes and Fees: This ordinance establishes the building and construction standards that include those addressing erosion, runoff, drainage, flood control and water safety. In particular, it also includes requirements for preparation of a Storm Water Pollution Prevention Plan (SWPPP) for construction sites, implementation of year-round best management practices (BMPs) on such sites and the monitoring and maintaining of the BMPs to ensure they continue to provide adequate stormwater flow/runoff protections, erosion protection and sediment controls, both during and after construction activities on a site. These measures all help protect water quality.

Ordinance No. 458 – Regulating Flood Hazard Areas and Implementing the National Flood Insurance Program: This ordinance enacts measures that ensure that water and wastewater systems are adequately protected from flooding and would not contaminate or be contaminated by floodwaters. Thus, Ordinance No. 458 protects water supplies and water quality for both surface and groundwater.

Ordinance No. 592 – Regulating Sewer Use, Sewer Construction and Industrial Wastewater Discharges in County Service Areas: This ordinance sets various standards for sewer use, construction and industrial wastewater discharges within Riverside County to protect both water quality and the infrastructure conveying and treating these wastewaters. As a result, Ordinance No. 592 protects water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 617– Hazardous Substances (Regulating Underground Storage Tanks): This ordinance provides for a program for the prevention of contamination from improper storage of hazardous substances stored underground. It also establishes and a Local Oversight Program for the unauthorized releases of petroleum and petroleum-related materials from leaking underground tank systems which require remedial action and requires remediation of unauthorized releases. Thus, Ordinance No. 617 serves to prevent long-term threats to the public health, water quality and local water supplies (surface and groundwater) from underground tank systems.

Ordinance No. 629 – Prohibiting Bathing, Swimming, Boating or Entering Irrigation Canals, Ditches or Drains in Unincorporated Areas of Palo Verde Valley: This ordinance protects water quality and water supplies in the Palo Verde Valley by making it unlawful for any person to "bathe, swim, boat, water-ski or otherwise enter into" the water in any irrigation canal, lateral, ditch or drain in the unincorporated area of the Palo Verde Valley, coterminous with the Palo Verde Irrigation District.

Ordinance No. 650 – Sewer Discharge in Unincorporated Territory: This ordinance prohibits the discharge of sewage and sewage effluent into any waterbody above or below ground within Riverside County. It also establishes a variety of regulations regarding sewer connections and OWTS. In this way, Ordinance No. 650 protects water supplies, water and wastewater facilities and water quality.

Ordinance No. 682 – Construction, Reconstruction, Abandonment and Destruction of Wells: This ordinance establishes minimum standards for construction, reconstruction, abandonment and destruction of wells in order to protect underground water resources and provide safe water within Riverside County by requiring county permits for these activities. As a result, Ordinance No. 682 protects water supplies, as well as water quality, for groundwater.

Ordinance No. 754 - Stormwater/Urban Runoff Management and Discharge Controls: This ordinance protects the health, safety and general welfare of Riverside County residents by imposing restrictions to regulate discharges to stormdrain systems and reduce pollutants entering storm drains (and, ultimately, surface and groundwater within Riverside County). As a result, this ordinance protects and enhances the water quality of county watercourses, water bodies, groundwater and wetlands.

Ordinance No. 830 – Regulating the Land Application of Class A Sewage Sludge for Agricultural Activities: Ordinance No. 830 regulates the application of bulk Class A sewage sludge in commercial farming uses to ensure it does not adversely affect public health, ground and surface water or soils. Through these regulations, this ordinance serves to protect water supplies and water quality for both surface water and groundwater.

Ordinance No. 843 – Regulating the Discharge of Wastes into the Public Sewer System for the Highgrove Community: This ordinance regulates the discharge of wastes into the sewage collection systems of the Highgrove community and protects water supplies, water and wastewater facilities, and water quality for both surface water and groundwater.

Ordinance No. 856 – Establishing a Septic Tank Prohibition for Specified Areas of Quail Valley and Requiring the Connection of Existing Septic Systems to Sewer: This ordinance protects groundwater quality in the Quail Valley region of Riverside County by prohibiting new septic systems and modifications to existing systems. These prohibitions and restrictions protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater in the region, as well as for Canyon Lake (a designated 'impaired waterbody' due to sewage runoff) and the water users relying on it as a water supply source.

Ordinance No. 871 – Prohibiting the Installation of Specified Septic Tank Systems in Cherry Valley: This ordinance was enacted to protect water quality in the Cherry Valley region of Riverside County from high nitrate levels in drinking water as a result of failing septic systems. Limitations enacted by this ordinance (i.e., septic prohibitions) protect water supplies and groundwater quality in the region. It does so by prohibiting additional septic systems.

c. Compliance with Existing General Plan Policies

The following existing policies of the Riverside County General Plan would help reduce significant water quality impacts. See Section 4.19.5.D for full text of each of these policies.

Policies OS 3.1-3.3: These policies address wastewater treatment and protection of water quality through compliance with various pollution discharge standards.

Policies OS 6.1 and 6.3: These policies address protection of wetlands and other riparian resources from hydrological disruption, protect water quality within floodplains and drainages, and minimize erosion effects.

d. Compliance with Proposed New or Revised General Plan Policies

The following proposed new or revised policies of the Riverside County General Plan would address potential impacts to water quality. See Section 4.19.5.D for full text of each of these policies.

New Policies OS 3.4-3.7: These policies address requirements to comply with NPDES and other regulations addressing pollution discharges and runoff to protect stormwater quality and, ultimately surface and groundwater fed by stormwater runoff.

Policies LU 9.1, 9.2 and 9.4: These policies address protection of wetlands and other riparian resources from hydrological disruption, protect water quality within floodplains and drainages, and minimize erosion effects.

e. Compliance with Mitigation Measures from EIR No. 441

In addition to the below specific mitigation measures from EIR No. 441 that address water quality directly, existing Mitigation Measures 4.17.5A (from Impact 4.19.E), 4.17.5B (from Impact 4.19.D) and 4.17.5E (from Impact 4.19.I) would also aid in reducing impacts to water quality.

Existing Mitigation Measure 4.17.5C: Where development may contribute to a worsening of local or regional ground or surface water quality (as determined by the Riverside County Department of Environmental Health and/or RWQCB), a water quality analysis shall be prepared. The water quality analysis shall include (but shall not be limited to): an analysis of existing surface and subsurface water quality; an assessment of how the proposed development would affect existing water quality; an assessment of how the proposed development would affect beneficial uses of the water; and specific measures to limit or eliminate potential water quality impacts and/or

impacts to beneficial uses of ground/surface water. Where determined necessary by the County [of Riverside] or other responsible entity, the water quality analysis shall include, at an equal level of detail, potential impacts to tributary or downstream areas. The water quality analysis shall be submitted to the County [of Riverside] and the RWCQB for review and shall be approved prior to the issuance of any entitlement that would result in the physical modification of the project site.

Existing Mitigation Measure 4.17.5D: The project applicant shall submit to the County [of Riverside] and the RWQCB, for review and approval, evidence that the specific measures to limit or eliminate potential water quality impacts resulting from the entire development process, will be implemented as set forth in the water quality analysis. Said evidence shall be submitted and approved prior to the issuance of any entitlement that would result in the physical modification of the project site.

3. Finding on Significance for Impact 4.19.C

With the implementation of the above regulations, ordinances, existing and proposed General Plan policies and mitigation measures from EIR No. 441, GPA No. 960 would have a less than significant impact on water quality.

D. Would the project violate any water quality standards or waste discharge requirements?

Impact 4.19.D – Violate Water Quality Standards or Waste Discharge Requirements: Future development accommodated by the land use and policy changes proposed by the project, GPA No. 960, has the potential to result in alterations to existing hydrology, increases in impervious surfaces and increases in urban runoff. Such changes would increase the discharge of pollutants into receiving waters if not properly managed and controlled. Thus, compliance with existing laws, regulatory programs, ordinances, General Plan policies and existing mitigation measures from EIR No. 441, are necessary to ensure that this impact is less than significant.

1. Analysis of Impact 4.19.D

Future development accommodated by the project would result in alterations to existing hydrology and increases in surface water flows due to urban runoff. If not properly managed and controlled, urbanization may change stream hydrology and increase pollutant loading to receiving waters. As a watershed undergoes urbanization, pervious surface area decreases, runoff volume and velocity may increase, riparian habitat and wetlands are lost, the frequency and severity of flooding may increase, as would pollutant loading. Most of these impacts occur due to human (anthropogenic) activities that occur during and/or after urbanization. These pollutants and hydrologic changes may cause declines in aquatic resources, cause toxicity to aquatic organisms and affect human health and the environment. It is also possible that in semi-arid regions development may result in a net increase in absorption. Impaired waterbodies in Riverside County (see Table 4.19-C) could be affected by future project-related development upstream if pollutant discharges occur.

Section 4.19.7 outlines theoretical wastewater generation potential associated with project build out. See, in particular, Table 4.19-BL. Water quality problems in Riverside County have been related to inadequate subsurface sewage disposal, waste disposal management of the Santa Ana River watershed, agricultural operations (e.g., agricultural runoff), the buildup of sediment resulting from construction-related erosion and urban stormwater runoff. The RWQCBs provide state-level water quality policy for Riverside County. Also, the NPDES permit process mandates the use of BMPs to minimize the adverse effects of pollution and to protect water quality.

To protect (or restore) water quality, the RWQCBs enforce the CWA through the NPDES, as well as the State of California's Water Codes. Pursuant to these regulations, permits from the applicable RWQCB are required for a wide variety of activities with potential to discharge wastes into Waters of the State or U.S. These include construction and operational activities, particularly operation of MS4s (municipal separate storm sewer systems) and industries that produce wastewater. As described in Section 4.19.2.E, the County of Riverside operates its MS4s under permits from the three RWQCBs with jurisdictions in Riverside County.

All construction activities are required to obtain and comply with NPDES permits, SWPPPs and Water Quality Management Plans (WQMPs) to prevent or minimize construction-related water quality impacts and waste discharges, particularly as related to soils, i.e., erosion, sedimentation and fill deposition. All developed uses conveying water into existing stormdrain systems have to comply with County of Riverside MS4 permit conditions and the associated Master Drainage Plan standards (if applicable). Projects must also comply with CWA Sections 401 and 404 if waters of the U.S. would be disturbed. Riverside County regulations addressing runoff and requiring no net increase of flow from onsite would also apply. Compliance with the extensive water quality regulations and programs, particularly those of the NPDES, would ensure no significant violations of water quality standards or waste discharge requirements occur. Compliance with these regulations and programs are assured through conditions of approval issues by the County of Riverside for implementing projects.

2. Regulatory Compliance Affecting Impact 4.19.D

The adverse water quality and waste discharge effects associated with future development accommodated by the project would be avoided, reduced or minimized through adherence to and compliance with the following regulations, policies and existing mitigation measures.

a. Compliance with Federal and State Regulations

Compliance with the following state and federal regulations would help reduce impacts due to water quality and waste discharges.

Federal Water Pollution Control Act of 1972 (aka the Clean Water Act): As described above, this collection of regulations provide strong water quality protection, including establishing the NPDES program to protect watersheds from runoff and waste discharges. They ensure that water quality is protected and water sources remain safe and suitable for use.

CWA Section 402 – National Pollutant Discharge Elimination System: The CWA's NPDES permit program focuses on discharges from municipal wastewater plants, but also applies to industrial discharges, construction site dewatering discharges and stormwater discharges to surface waters. Municipalities, publicly-owned treatment works and most industries in the U.S. are required to obtain an NPDES permit for discharges, including stormwater runoff. NPDES permits regulate discharge of "pollutants from point sources to waters of the United States" to protect surface water quality and their beneficial use. The responsibility for issuing NPDES permits in California has been delegated to the RWQCBs; three of which have jurisdiction in Riverside County. See Section 4.19.2.E.

Federal Safe Drinking Water Act: Compliance with the EPA's minimum standards set under this act serves to protect tap water from potentially harmful contaminants. Compliance with this act helps protect water quality and viability of existing and future drinking water supplies.

California Porter-Cologne Water Quality Control Act of 1970: As mentioned above, compliance with the regulations of this act serves to protect surface and groundwater sources from pollutant discharges, runoff and erosion, and other activities that would adversely affect water supplies. The RWQBCs and waste discharge requirements are also organized under this law.

b. Compliance with Existing Riverside County Regulations

Compliance with the following Riverside County regulations would prevent or reduce significant violations of water quality standards or waste discharge requirements. These regulations are already in effect in Riverside County and are not part of the project, GPA No. 960. Rather, these policies are considered to play a role in ensuring any potential environmental effects are avoided, reduced or minimized through their application on a case-by-case basis. The County of Riverside has existing programs in place that ensure applicable policies are imposed once a development proposal triggers a specific policy or policies. The need for specific policies is determined through subsequent site-specific CEQA analysis performed at the time of implementing project review. These measures are implemented, enforced and verified through their inclusion into project conditions of approval.

Ordinance No. 457 - Building Codes and Fees: This ordinance establishes the building and construction standards including those addressing runoff, erosion, drainage and flood control. In particular, it includes requirements for preparation of a Storm Water Pollution Prevention Plan (SWPPP) for construction sites, implementation of year-round best management practices (BMPs) and the monitoring and maintaining the BMPs to ensure they provide adequate stormwater flow/runoff protection and erosion control, both during and after construction.

Ordinance No. 458 - Regulating Flood Hazard Areas and Implementing the National Flood Insurance Program: This ordinance enacts the National Flood Insurance Program to protect the public's health, safety and welfare from flooding hazards within Riverside County. It does so by regulating development within flood hazard areas and establishing a variety of land use and construction standards for such development. It serves to protect water supplies by requiring water and sewer lines be constructed to withstand various flood hazards to minimize infiltration of floodwaters into the systems. Thus, it protects the water quality of both the water supplies serving development and the surface waters that would be contaminated by sewer line damage in the event of a flood. It also requires provisions of adequate drainage and obtainment of all other required state and federal permits. Together these measures ensure that water and wastewater systems are adequately protected from flooding and would not contaminate or be contaminated by floodwaters. Thus, Ordinance No. 458 serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 592 – Regulating Sewer Use, Sewer Construction and Industrial Wastewater Discharges in County Service Areas: This ordinance sets various standards for sewer use, construction and industrial wastewater discharges within Riverside County. As a result, Ordinance No. 592 serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 617– Hazardous Substances (Regulating Underground Storage Tanks): This ordinance establishes a program to prevent contamination from improper storage of hazardous substances underground to prevent long-term threats to the public health, water quality and local water supplies (surface and groundwater) from underground tank systems.

Ordinance No. 629 – Prohibiting Bathing, Swimming, Boating or Entering Irrigation Canals, Ditches or Drains in Unincorporated Areas of Palo Verde Valley: This ordinance protects water quality and water

supplies in the Palo Verde Valley by banning human water-contact activities in any irrigation canal, lateral, ditch or drain in the unincorporated area of the Palo Verde Valley.

Ordinance No. 650 – Sewer Discharge in Unincorporated Territory: This ordinance prohibits the discharge of sewage and sewage effluent into any waterbody above or below ground within Riverside County. It also establishes a variety of regulations regarding sewer connections and OWTS. In this way, Ordinance No. 650 protects water supplies, water and wastewater facilities and water quality.

Ordinance No. 682 – Construction, Reconstruction, Abandonment and Destruction of Wells: This ordinance establishes minimum standards for construction, reconstruction, abandonment and destruction of wells in order to protect underground water resources and provide safe water within Riverside County.

Ordinance No. 754 - Stormwater/Urban Runoff Management and Discharge Controls: This ordinance regulates discharges to stormdrain systems and pollutants entering storm drains (and, ultimately, surface and groundwater within Riverside County). Among other things, the ordinance requires that all discharge to storm drain systems be confined to stormwater runoff discharged pursuant to a NPDES permit and RWQCB authorization. Thus, Ordinance No. 754 mitigates impacts from stormwater flow, runoff and pollutants carried by them, as well as their effects on water quality.

Ordinance No. 843 – Regulating the Discharge of Wastes into the Public Sewer System for the Highgrove Community: This ordinance regulates the discharge of wastes into the sewage collection systems of the Highgrove community and protects water supplies, water and wastewater facilities, and water quality for both surface water and groundwater.

Ordinance No. 856 – Establishing a Septic Tank Prohibition for Specified Areas of Quail Valley and Requiring the Connection of Existing Septic Systems to Sewer: This ordinance protects groundwater quality in the Quail Valley region of Riverside County by prohibiting new septic systems and modifications to existing systems. These prohibitions and restrictions protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater in the region, as well as for Canyon Lake (a designated 'impaired waterbody' due to sewage runoff) and the water users relying on it as a water supply source.

Ordinance No. 871 – Prohibiting the Installation of Specified Septic Tank Systems in Cherry Valley: This ordinance was enacted to protect water quality in the Cherry Valley region of Riverside County from high nitrate levels in drinking water as a result of failing septic systems. Limitations enacted by this ordinance (i.e., septic prohibitions) protect water supplies and groundwater quality in the region. It does so by prohibiting additional septic systems.

Program Funding: The County of Riverside and cities collect taxes, fees and other revenue that is used to fund MS4 permit compliance program activities, as well as other water quality protection programs. These include assessment areas, such as the Whitewater River Watershed Benefit Assessment Area, which were established as funding sources for MS4 permit (and individual NPDES) compliance. In the Whitewater case, assessments are calculated on the basis of proportional stormwater runoff and are enrolled on the property tax bills generated by the Riverside County Tax Assessor's office. Some County Service Areas (CSAs), for example CSA 152, also collect funds similarly or use general ('ad valorem') tax revenues to finance stormwater management programs.

c. Compliance with Existing General Plan Policies

The following existing policies of the Riverside County General Plan would help reduce significant water quality impacts. See Section 4.19.5.D for full text of each of these policies.

Policies OS 3.1-3.3: These policies address wastewater treatment and protection of water quality through compliance with various pollution discharge standards.

Policies OS 6.1 and 6.3: These policies address protection of wetlands and other riparian resources from hydrological disruption, protect water quality within floodplains and drainages, and minimize erosion effects.

d. Compliance with Proposed New or Revised General Plan Policies

The following proposed new or revised policies of the Riverside County General Plan would address potential impacts to water quality. See Section 4.19.5.D for full text of each of these policies.

New Policies OS 3.4-3.7: These policies address requirements to comply with NPDES and other regulations addressing pollution discharges and runoff to protect stormwater quality and, ultimately surface and groundwater fed by stormwater runoff.

Policies LU 9.1, 9.2 and 9.4: These policies address protection of wetlands and other riparian resources from hydrological disruption, protect water quality within floodplains and drainages, and minimize erosion effects.

e. Compliance with Mitigation Measures from EIR No. 441

In addition to the below specific mitigation measures from EIR No. 441 that address wastewater treatment issues directly, existing Mitigation Measure 4.17.5E (described under Impact 4.19.I) and Mitigation Measures 4.10.9A (described under Impact 4.19.H), would also aid in reducing wastewater impacts.

Existing Mitigation Measure 4.17.5A: The development of septic systems shall be in accordance with applicable standards established by Riverside County and other responsible authorities.

Existing Mitigation Measure 4.17.5B: Point source pollution reduction programs shall fully adhere to applicable standards required by federal, state and local agencies. Prior to the approval of individual projects, Riverside County shall verify that the provisions of applicable point source pollution programs have been satisfied.

Existing Mitigation Measure 4.17.5C: Where development may contribute to a worsening of local or regional ground or surface water quality (as determined by the Riverside County Department of Environmental Health and/or RWQCB), a water quality analysis shall be prepared. The water quality analysis shall include (but shall not be limited to): an analysis of existing surface and subsurface water quality; an assessment of how the proposed development would affect existing water quality; an assessment of how the proposed development would affect beneficial uses of the water; and specific measures to limit or eliminate potential water quality impacts and/or impacts to beneficial uses of ground/surface water. Where determined necessary by the County [of Riverside] or other responsible entity, the water quality analysis shall include, at an equal level of detail, potential impacts to tributary or downstream areas. The water quality analysis shall be submitted to the County [of Riverside] and the RWCQB for review and shall be approved prior to the issuance of any entitlement that would result in the physical modification of the project site.

Existing Mitigation Measure 4.17.5D: The project applicant shall submit to the County [of Riverside] and the RWQCB, for review and approval, evidence that the specific measures to limit or eliminate potential water quality impacts resulting from the entire development process, will be implemented as set forth in the water quality

analysis. Said evidence shall be submitted and approved prior to the issuance of any entitlement that would result in the physical modification of the project site.

3. Finding on Significance for Impact 4.19.D

With the implementation of the above-listed existing regulations, existing and proposed General Plan policies, existing mitigation measures from EIR No. 441, GPA No. 960 would have a less than significant impact on water quality in relationship to compliance with the water quality standards and waste discharge requirements.

E. Would the project exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board?

Impact 4.19.E – Exceed Wastewater Treatment Requirements: Future development accommodated by the land use and policy changes proposed by the project, GPA No. 960, has the potential to increase the amount of people and structures generating wastewater. Wastewater requires proper treatment to ensure it does not adversely affect receiving waters, for example, by elevating pollutant levels or introducing pathogens. Receiving waters are protected through Riverside County's compliance with and enforcement of its NPDES MS4 permits, as well as other permits required for a wide variety of activities with potential to discharge wastes into Waters of the State or U.S. These include construction and operational activities, operation of MS4s (municipal separate storm sewer systems) and industries that produce wastewater. Compliance with the NPDES program and permits, as well as other laws, regulations, ordinances, General Plan policies and existing mitigation measures from EIR No. 441, would be sufficient to ensure that this impact is less than significant.

1. Analysis of Impact 4.19.E

As outlined above under Impact 4.19.D, wastewater generated in Riverside County must be disposed of pursuant to the NPDES program, when applicable, which covers a variety of construction and post-construction activities. As described in Section 4.19.2.E, the County of Riverside operates its MS4s under permits from the three RWQCBs with jurisdictions in Riverside County.

Where connected to municipal sanitary sewer systems are not available, development must rely on various types of septic systems (OWTS – onsite waste treatment systems). As described in Section 4.19.2.D, these systems typically result in percolation of wastewater into groundwater or, occasionally, to surface waters. Regulation by the State of California and County of Riverside ensures that such systems are installed correctly and operate safely to prevent health risks or environmental harm. Sanitary sewer collection systems deliver sewage to municipal (or other agency) treatment plants where the waste is treated per applicable standards. Table 4.19-BH list the wastewater treatment plants operating in Riverside County.

As outlined in Section 4.19.5 and throughout this section as well, extensive regulation by the County of Riverside, RWQCBs and other state agencies, as well as the U.S. EPA, would ensure that future development accommodated by the project does not exceed any RWQCB wastewater treatment requirements. In addition, the County of Riverside has ordinances that strictly regulate the construction and maintenance of septic tanks. Section 8.124.030 of the County of Riverside Government Code states that all septic facilities require written approval for construction from the Riverside County Health Officer. Approval for septic tanks require detailed review and onsite inspections, which include a scaled, contoured plot plan, a soils feasibility report that adequately evaluates soil percolation, a special feasibility boring report (for groundwater and/or bedrock) and engineered topographical map.

Additionally, the U.S. EPA has established standards governing the placement of septic systems in the proximity of water supply wells. The EPA's 'Zone A' is classified as a potential area of direct microbiological and chemical contamination based on an estimated two-year time of (contaminant) travel within an aquifer from the wellhead to the potential source of contamination. Waste discharges from conventional septic tank/subsurface disposal systems may adversely affect both the quality and beneficial uses of the water and/or violate local, regional or state water quality standards.

As excerpted from EPA's Design Manual Onsite Wastewater Treatment and Disposal Systems, "State Codes that specify 100-foot separation distances between convention subsurface wastewater infiltration system treatment units and down-gradient wells or surface waters should not be expected to always protect these resources from dissolved, highly mobile contaminants...published data indicate that viruses that reach groundwater can travel at least 220 vertical feet and 1,338 feet laterally in some porous soils and still remain effective." This standard is explicitly addressed by existing EIR No. 441 Mitigation Measure 4.15.4A (see below) to ensure that water wells are protected from septic tanks being placed too close to them.

2. Regulatory Compliance Affecting Impact 4.19.E

The adverse effects associated with wastewater treatment needs would be avoided, reduced or minimized through adherence to and compliance with the following regulations, policies and existing mitigation measures.

a. Compliance with Federal and State Regulations

Compliance with the following state and federal regulations would help ensure compliance with wastewater treatment requirements.

Federal Water Pollution Control Act of 1972 (aka the Clean Water Act): As described further under Impact 4.19.C, these regulations ensure that the water quality of is protected and that surface and groundwater sources remain safe and suitable for use as drinking water, irrigation water, recharge water and other beneficial uses.

CWA Section 402 – National Pollutant Discharge Elimination System: The CWA's NPDES permit program focuses on discharges from municipal wastewater plants, but also applies to industrial discharges, construction site dewatering discharges and stormwater discharges to surface waters. Municipalities, publicly owned treatment works and most industries in the U.S. are required to obtain an NPDES permit for discharges, including stormwater runoff. NPDES permits regulate discharge of "pollutants from point sources to waters of the United States" to protect surface water quality and their beneficial use. The responsibility for issuing NPDES permits in California has been delegated to the RWQCBs – three of which have jurisdiction in Riverside County. See Section 4.19.2.E for details.

California Porter-Cologne Water Quality Control Act of 1970: As mentioned above, compliance with this act helps improve impaired waterbodies, prevent pollutant discharges and other activities that would adversely affect surface or groundwater. The protections of this act enhance water quality and ensure that surface and groundwater sources remain safe and suitable for use.

CCR Title 22 – Recycled Water: Chapter 4 of CCR Title 22 establishes recycled water quality standards and treatment reliability criteria that apply to recycling of wastewater. Processing of recycled water in compliance with these standards makes additional water supply available that meets all applicable state and federal water quality standards.

b. Compliance with Existing Riverside County Regulations

Compliance with the following Riverside County regulations would prevent or reduce significant impacts associated with wastewater treatment. These regulations are already in effect in Riverside County and are not part of the project, GPA No. 960. Rather, these policies are considered to play a role in ensuring any potential environmental effects are avoided, reduced or minimized through their application on a case-by-case basis. The County of Riverside has existing programs in place that ensure applicable policies are imposed once a development proposal triggers a specific policy or policies. The need for specific policies is determined through subsequent site-specific CEQA analysis performed at the time of implementing project review. These measures are implemented, enforced and verified through their inclusion into project conditions of approval.

Ordinance No. 457 – Building Codes and Fees: This ordinance establishes the building and construction standards including those addressing runoff, erosion, drainage and flood control. In particular, it includes requirements for preparation of a Storm Water Pollution Prevention Plan (SWPPP) for construction sites, implementation of year-round best management practices (BMPs) and the monitoring and maintaining the BMPs to ensure they provide adequate stormwater flow/runoff protection and erosion control, both during and after construction.

Ordinance No. 458 – Regulating Flood Hazard Areas and Implementing the National Flood Insurance Program: Compliance with Ordinance No. 458 serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 461 – Road Improvement Standards: Compliance with this ordinance prevents significant adverse impacts due to road construction, runoff and stormwater flows from roadways, as well as water erosion.

Ordinance No. 592 – Regulating Sewer Use, Sewer Construction and Industrial Wastewater Discharges in County Service Areas: This ordinance sets various standards for sewer use, construction and industrial wastewater discharges within Riverside County to protect both water quality and the infrastructure conveying and treating these wastewaters. Ordinance No. 592 protects water quality by prohibiting discharges to public sewers (which directly or indirectly connects to Riverside County's sewerage system) of any wastes that may have an adverse or harmful effect on sewers, maintenance personnel, wastewater treatment plant personnel or equipment, treatment plant effluent quality, public or private property or may otherwise endanger the public, the local environment or create a public nuisance. As a result, Ordinance No. 592 serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 617– Hazardous Substances (Regulating Underground Storage Tanks): This ordinance establishes a program to prevent contamination from improper storage of hazardous substances underground to prevent long-term threats to the public health, water quality and local water supplies (surface and groundwater) from underground tank systems.

Ordinance No. 650 – Sewer Discharge in Unincorporated Territory: This ordinance protects water quality, storm drains and surface waters by prohibiting the discharge or deposition of any sewage, sewage effluent or non-hazardous waste, treated or untreated, into any streams or bodies of water above or below the ground, within Riverside County. It also establishes a variety of regulations regarding sewer connections and OWTS (loosely, septic systems and other localized sewer systems). In this way, Ordinance No. 650 protects water supplies, water and wastewater facilities and water quality for both surface water and groundwater from sewage-related pollutants, such as bacteria and pathogens.

Ordinance No. 754 – Stormwater/Urban Runoff Management and Discharge Controls: This ordinance regulates discharges to stormdrain systems and pollutants entering storm drains (and, ultimately, surface and groundwater within Riverside County). Among other things, the ordinance requires that all discharge to storm drain systems be confined to stormwater runoff discharged pursuant to a NPDES permit and RWQCB authorization. Thus, Ordinance No. 754 mitigates impacts from stormwater flow, runoff and pollutants carried by them, as well as their effects on water quality.

Ordinance No. 843 – Regulating the Discharge of Wastes into the Public Sewer System for the Highgrove Community: This ordinance regulates the discharge of wastes into the sewage collection systems of the Highgrove community as these effluents are channeled to the City of Riverside's Regional Water Quality Control Plant and ultimately discharged into permeable soil and/or surface waters of the Santa Ana River. Among other things, it establishes sewage effluent discharge limitations and requirements to comply with federal general pretreatment regulations. In this way Ordinance No. 843 protects water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 856 – Establishing a Septic Tank Prohibition for Specified Areas of Quail Valley and Requiring the Connection of Existing Septic Systems to Sewer: This ordinance protects water quality for groundwater in the Quail Valley region by prohibiting new septic systems and modifications to existing systems. The prohibitions and restrictions of Ordinance No. 856 also help protect water supplies, water and wastewater facilities, and water quality for surface water in the Quail Valley region, as well as Canyon Lake (a designated 'impaired waterbody' due to sewage runoff) and the water users relying on it as a water supply source.

Ordinance No. 871 – Prohibiting the Installation of Specified Septic Tank Systems in Cherry Valley: This ordinance was enacted to protect water quality in the Cherry Valley region of Riverside County from high nitrate levels in drinking water as a result of failing septic systems. It prohibits new septic systems and expansions or modifications of existing septic systems within the region because of septic system failures likely contributing to excessive nitrate levels in the region's groundwater. Only septic system designs that can effectively reduce (i.e., 50% or more) effluent nitrate levels and not lead to further degradation of the groundwater may be approved by the County of Riverside. Through these restrictions, this ordinance protects water supplies and groundwater quality in the region.

c. Compliance with Existing General Plan Policies

Implementation of these water resource-related General Plan policies would help reduce the effects of future development on wastewater collection and treatment infrastructure. See Section 4.19.5.D for full text of each of these policies.

Policies OS 3.1-3.3: These policies address wastewater treatment and protection of water quality through compliance with various pollution discharge standards.

Policies LU 5.3, 21.2, 28.3, 29.7, 30.7, 31.4 and 32.6: These policies address project consistency with urban water management plans and require projects be reviewed to ensure water resources and infrastructure are adequate for the proposed level of development.

d. Compliance with Proposed New or Revised General Plan Policies

The following proposed new or revised policies of the Riverside County General Plan would address potential impacts to water resources. See Section 4.19.5.D for full text of each of these policies.

New Policies OS 3.4-3.7: These policies address requirements to comply with NPDES and other regulations addressing pollution discharges and runoff to protect stormwater quality and, ultimately surface and groundwater fed by stormwater runoff.

New Policy LU 22.2: This policy ensures water resources are adequate for the proposed level of development.

e. Compliance with Mitigation Measures from EIR No. 441

In addition to the below specific mitigation measures from EIR No. 441 that address wastewater treatment issues directly, existing Mitigation Measure 4.17.5E (item h, in particular), described under Impact 4.19.I, would also aid in reducing impacts from wastewater.

Existing Mitigation Measure 4.15.4A: Conventional septic tanks/subsurface disposal systems shall be prohibited within any designated Zone A of an EPA wellhead protection area. Where a difference between Riverside County and EPA septic tank setback distance requirements exists, the EPA standard shall apply.

Existing Mitigation Measure 4.17.5A: The development of septic systems shall be in accordance with applicable standards established by Riverside County and other responsible authorities.

Existing Mitigation Measure 4.10.9A: Riverside County, where required, and in accordance with issuance of a National Pollutant Discharge Elimination System (NPDES) permit, shall require the construction and/or grading contractor for individual developments to establish and implement specific Best Management Practices (BMPs) at time of project implementation.

f. New EIR Compliance Measures

In order to ensure impacts are fully mitigated to less than significant, the following new mitigation measure is proposed. It is a revision to the previous EIR No. 441 Mitigation Measure 4.15.4A that indicates the more restrictive standard shall apply between the EPA and Riverside County standards in effect. Since EIR No. 441 mitigation measures cannot be revised (they were certified for a specific document, i.e., the 2003 RCIP General Plan), this "new" measure is necessary, even though it is merely an update.

NEW **Mitigation Measure 4.19.E-N1:** Conventional septic tanks/subsurface disposal systems shall be prohibited within any designated Zone A of an EPA wellhead protection area. Where a difference between Riverside County and EPA septic tank setback distance requirements exists, the more restrictive standard shall apply.

3. Finding on Significance for Impact 4.19.E

With implementation of regulations, existing and proposed General Plan policies and existing mitigation measures from EIR No. 441, plus new measure 4.19.E-N1, future development accommodated by GPA No. 960 would have less than significant impacts due to exceeding RWQCB wastewater treatment requirements.

F. Would the project result in a determination by a wastewater treatment provider which serves or may serve the project that it would not have adequate capacity to serve the project's projected demand in addition to the provider's existing commitments?

Impact 4.19.F – Exceed Wastewater Treatment Capacity: Future development accommodated by the land use and policy changes proposed by the project, GPA No. 960, has the potential to contribute to increased generation of wastewater needing treatment, the provision of which could exceed the existing capacity of the treatment facility. In addition, where sanitary sewer connection and treatment are not available, septic systems would be necessary. The proliferation of septic systems in rural communities may potentially contaminate groundwater with nitrates, ammonia, salts, metals, organic solvents, grease and oil, and other substances, impairing the beneficial uses of local water supplies. Compliance with existing laws, regulatory programs, ordinances, General Plan policies and existing mitigation measures from EIR No. 441 would be sufficient to ensure that impacts associated with wastewater treatment capacities are less than significant.

1. Analysis of Impact 4.19.F

Future development accommodated by the project would generate increased population and housing, as well as commercial and industrial land uses. This growth would incrementally increase the amount of wastewater generated, which would necessitate increased wastewater treatment capacity.

As shown in Tables 4.19-BI and 4.19-BJ, future development accommodated by GPA No. 960 has the potential to occur within and affect 111,400 acres of unincorporated Riverside County, including approximately 18,800 acres within the boundaries of existing water districts and other agencies that provide sanitary sewer services. The Mecca Sanitary District service 260 acres within eastern Riverside County. And, at least 92,600 acres are not served by sanitary sewer districts or any other sewer providers. And, even within provider service areas, not all customers may have sanitary sewer services available.

Within the three categories of spatial project components analyzed, the 'Potentially Affected' area, which has the greatest potential to generate additional wastewater (because it generally represents foreseeable areas of increasing development potential), totals 7,900 acres and is associated with a theoretical wastewater generation increase of approximately 1.6 million gallons per day (mgpd) above baseline conditions at project build out. Of this amount, approximately 42% would be generated by the urban and urbanizing areas of western Riverside County generally (though not always) served with sanitary sewer collection and wastewater treatment by existing water and sewer districts. In particular, this includes EMWD and WMWD.

Another 26% would be located in the urbanizing regions of the Coachella Valley. The DVWD provides the bulk of the wastewater treatment services in this region. The remaining 32% would be located in areas without sanitary sewer service and would typically rely on individual septic systems (OWTS) or, possibly, small community collectives. This includes the communities within the San Gorgonio Pass and San Jacinto Mountains (except for the Idyllwild village center, which has sanitary sewer provided by Idyllwild Water District), and the far eastern desert communities near the Arizona border. New uses in these areas would not affect existing or future wastewater treatment facilities, but would instead require construction of individual OWTS as part of their implementation. This assumes geology, hydrology, topography, soils, etc., are suitable for OWTS; not all sites will be. Where OWTS are not feasible, wastewater would have to be stored onsite and then periodically transported (i.e., by truck) to an appropriate wastewater treatment facility. Or, failing that, a site could possibly be undevelopable.

As described in Section 4.19.4.J, in some areas, Riverside County's wastewater treatment facilities may have forecast generation totals that exceed the available (or projected) treatment capacities. Where demand for wastewater treatment exceeds the agency's treatment plant capacity, a significant impact would occur. In general, agencies plan future infrastructure needs, including for wastewater treatment, on the basis of a 5-year capital improvement program and use regional (for example, SCAG) and local demographics, as well as the general plans of affected cities and counties to determine their needs. As such, and with build out of GPA No. 960 projected for nearly 50 years hence, it is assumed that future development would occur incrementally over time and thus would not adversely affect the provision of wastewater treatment services over the long term. The additional wastewater treatment needs generated by future project implementation would not exceed the short (five-year) or long-term plans of existing providers nor outpace their ability to provide additional treatment capacity. Also, the construction of additional wastewater treatment plants, as well as water reclamation and storage facilities, would be subject to additional environmental analysis to determine onsite impacts. (See also, Impact 4.19.G.)

The wastewater service providers within Riverside County would continue to expand their treatment capacities consistent with growth projections and associated increased demand. Conservation methods and the increased use of reclaimed water would help decrease the need for treatment and storage capacity, and provide a beneficial reuse of water. Without the expansion of facilities to treat wastewater, development cannot occur on a long-term basis. However, it is feasible that adequate treatment capacity can be constructed to meet the increased demand and the overall effect of GPA No. 960 on municipal wastewater treatment capacity would be less than significant.

In the near future, the project would also contribute incrementally to the cumulative increase in need for wastewater treatment. This increased need, however, would be scattered across Riverside County and spread over roughly 50 years. As such, it would not result in a significant impact to wastewater treatment capacities.

Future development accommodated by the project would also allow and encourage development of rural residential and other land uses in areas that are not served by municipal sewer facilities. This is a potentially significant effect of the project. The regulatory measures described herein, however, would be sufficient to reduce the impact to less than significant. See, for example, Ordinance No.s 843, 856 and 871. Also, see discussion under Impact 4.19.E for more on septic system regulations.

2. Regulatory Compliance Affecting Impact 4.19.F

Adverse effects associated with potential demands on wastewater treatment facilities and capacities would be avoided, reduced or minimized through adherence to and compliance with the following regulations, policies and existing mitigation measures.

a. Compliance with Federal and State Regulations

Compliance with the following state and federal regulations would help reduce impacts due to demands on wastewater treatment facilities and capacities.

Federal Water Pollution Control Act of 1972 (aka the Clean Water Act): As described above, this collection of regulations provide strong water quality protection, including establishing the NPDES program to protect watersheds from runoff and waste discharges. They ensure that water quality is protected and water sources remain safe and suitable for use.

Federal Safe Drinking Water Act: Compliance with the EPA's minimum standards set under this act serves to protect tap water from potentially harmful contaminants. Compliance with this act helps protect water quality and viability of existing and future drinking water supplies.

California Porter-Cologne Water Quality Control Act of 1970: As mentioned above, compliance with this collection of regulations would protect surface and groundwater sources from wastewater and pollutant discharges, runoff and erosion, unpermitted hydrology disturbances and other activities that would adversely affect surface or groundwater.

CCR Title 22 - Recycled Water: Chapter 4 of CCR Title 22 establishes recycled water quality standards and treatment reliability criteria that apply to recycling of wastewater. Processing recycled water in compliance with these standards makes additional water supply available and ensures it meets all applicable state and federal water quality standards.

b. Compliance with Existing Riverside County Regulations

Compliance with the following Riverside County regulations would prevent or reduce significant impacts on wastewater treatment facilities and capacities.

Ordinance No. 458 - Regulating Flood Hazard Areas and Implementing the National Flood Insurance Program: This ordinance enacts measures that ensure that water and wastewater systems are adequately protected from flooding and would not contaminate or be contaminated by floodwaters. Thus, Ordinance No. 458 serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 592 – Regulating Sewer Use, Sewer Construction and Industrial Wastewater Discharges in County Service Areas: This ordinance sets various standards for sewer use, construction and industrial wastewater discharges within Riverside County to protect both water quality and the infrastructure conveying and treating these wastewaters. Ordinance No. 592 protects water quality by prohibiting discharges to public sewers (which directly or indirectly connects to Riverside County's sewerage system) of any wastes that may have an adverse or harmful effect on sewers, maintenance personnel, wastewater treatment plant personnel or equipment, treatment plant effluent quality, public or private property or may otherwise endanger the public, the local environment or create a public nuisance. As a result, Ordinance No. 592 serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 650 – Sewer Discharge in Unincorporated Territory: This ordinance protects water quality, storm drains and surface waters by prohibiting the discharge or deposition of any sewage, sewage effluent or non-hazardous waste, treated or untreated, into any streams or bodies of water above or below the ground, within Riverside County. It also establishes a variety of regulations regarding sewer connections and OWTS (loosely, septic systems and other localized sewer systems). In this way, Ordinance No. 650 protects water supplies, water and wastewater facilities and water quality for both surface water and groundwater from sewage-related pollutants, such as bacteria and pathogens.

Ordinance No. 754 - Stormwater/Urban Runoff Management and Discharge Controls: This ordinance regulates discharges to storm drain systems and pollutants entering storm drains (and, ultimately, surface and groundwater within Riverside County). Among other things, the ordinance requires that all discharge to storm drain systems be confined to stormwater runoff discharged pursuant to a NPDES permit and RWQCB authorization. Thus, Ordinance No. 754 mitigates impacts from stormwater flow, runoff and pollutants carried by them, as well as their effects on water quality.

Ordinance No. 843 – Regulating the Discharge of Wastes into the Public Sewer System for the Highgrove Community: This ordinance regulates discharge of waste into sewage collection systems in the Highgrove community, as these effluents are channeled to the City of Riverside's Regional Water Quality Control Plant and ultimately discharged into permeable soil and/or surface waters of the Santa Ana River. Among other things, it establishes sewage effluent discharge limitations and requirements to comply with federal general pretreatment regulations. In this way Ordinance No. 843 protects water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 856 – Establishing a Septic Tank Prohibition for Specified Areas of Quail Valley and Requiring the Connection of Existing Septic Systems to Sewer: This ordinance protects groundwater in the Quail Valley region of Riverside County by prohibiting new septic systems and modifications to existing systems. This protects water supplies, water and wastewater facilities and water quality for both surface water and groundwater in the Quail Valley region, as well as Canyon Lake (a designated 'impaired waterbody' due to sewage runoff contamination).

Ordinance No. 871 – Prohibiting the Installation of Specified Septic Tank Systems in Cherry Valley: This ordinance protects the Cherry Valley region from high nitrate levels in drinking water as a result of failing septic systems. It prohibits new septic systems and expansions or modifications of existing septic systems within the region because of septic system failures likely contributing to excessive nitrate levels in the region's groundwater. Only septic system designs that can effectively reduce (i.e., 50% or more) effluent nitrate levels and not lead to further degradation of the groundwater may be approved by the County of Riverside. Through these limitations, this ordinance serves to protect water supplies and groundwater quality in the region.

c. Compliance with Existing General Plan Policies

Although the General Plan does not include a Public Services Element, it does include a number of policies that address the effects of future development on wastewater facilities. The policies are already part of the General Plan and are not part of the project, GPA No. 960. They help ensure that potential environmental effects are avoided, reduced or minimized through their application on a case-by-case basis. The County of Riverside has existing programs in place that ensure applicable policies are imposed once a development proposal triggers a specific policy or policies. The need for specific policies is determined through subsequent site-specific CEQA analysis performed at the time of implementing project review. These measures are implemented, enforced and verified through their inclusion into project conditions of approval. See Section 4.19.5.D for full policy texts.

Policies OS 3.1-3.3: These policies address wastewater treatment and protection of water quality through compliance with various pollution discharge standards.

Policies LU 5.3, 21.2, 28.3, 29.7, 30.7, 31.4 and 32.6: These policies address project consistency with urban water management plans and require projects be reviewed to ensure water resources are adequate for the proposed level of development.

d. Compliance with New or Revised General Plan Policies

New Policy LU 22.2: This policy ensures water resources are adequate for the proposed level of development.

e. Compliance with Mitigation Measures from EIR No. 441

Existing Mitigation Measures 4.17.5D (listed under Impact 4.19.D), 4.15.4A and 4.10.9A (Impact 4.19.E), 4.9.1C (Impact 4.19.H) and 4.17.5E (Impact 4.19.I) would also aid in reducing impacts associated with wastewater treatment facilities.

3. Finding on Significance for Impact 4.19.F

With the implementation of the above regulations, ordinances, existing and proposed General Plan policies and existing mitigation measures from EIR No. 441, GPA No. 960 would have a less than significant impact on wastewater treatment facilities and capacities, as well as septic systems.

G. Would the project require or result in the construction of new water or wastewater facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?

Impact 4.19.G – Result in Significant Adverse Effects Due to the Construction of New or Expanded Water or Wastewater Facilities: Future development accommodated by the land use and policy changes proposed by the project, GPA No. 960, would result in increased demand for water supply, wastewater treatment and infrastructure to supply these services. These increases would contribute incrementally to the need for new or expanded water and wastewater treatment facilities. Since the project would be implemented on a case-by-case basis across many individual sites spread across Riverside County over roughly 50 years, however, it would not result in significant impacts tied to specific, inalterable areas. Rather, the future locations of such facilities can be established (located) so as to minimize potential environmental effects. Further, compliance with existing laws, regulatory programs, ordinances, General Plan policies and existing mitigation measures from EIR No. 441, would be sufficient to ensure that this impact is less than significant.

1. Analysis of Impact 4.19.G

As discussed under the prior impacts, future development accommodated by the project would result in increased demands for water supply, wastewater treatment and infrastructure to supply these services. See, for example, Tables 4.19-BG through 4.19-BN. These increases, however, would be spread throughout Riverside County and would occur incrementally over a roughly 50-year build out period. As a result, the project would not contribute significantly to the need for new or expanded water or wastewater treatment facilities in any specific given location. Rather, it is expected that individual future implementation projects would either be met by existing capacities or pay their fair-share costs towards providing needed additional capacity. Also, since GPA No. 960's changes are included in the Riverside County General Plan and agencies use general plans to help plan future infrastructure needs, it is expected that the agencies would be able to plan and build facilities to meet future needs accordingly. Further, since facilities are generally needed to serve regions, rather than specific locations, it is feasible that future facilities could be sited in a manner that avoids or minimizes significant environmental effects. Thus, for all these reasons, GPA No. 960's impact on the environment as a result of the need for new or expanded water and wastewater facilities would be less than significant.

2. Regulatory Compliance Affecting Impact 4.19.G

The adverse effects associated with the need for new or expanded water and wastewater facilities would be avoided, reduced or minimized through adherence to and compliance with the following regulations, ordinances, policies and existing mitigation measures.

a. Compliance with Federal and State Regulations

Compliance with the following state and federal regulations would help reduce impacts to the environment as a result of the need for new or expanded water and wastewater facilities.

Federal Safe Drinking Water Act: Compliance with the EPA's minimum standards set under this act serves to protect tap water from potentially harmful contaminants. Compliance with this act helps protect water quality and viability of existing and future drinking water supplies.

California Porter-Cologne Water Quality Control Act of 1970: As mentioned above, compliance with the various regulations and policies promulgated by the State of California pursuant to this act serve to protect or improve impaired waterbodies and eliminate or minimize pollutant discharges and other activities that would adversely affect surface and groundwater. Together, these protections protect water quality and ensure that surface and groundwater sources remain safe and suitable for use as drinking water, irrigation water, recharge water and other beneficial uses.

CCR Title 22 - Recycled Water: Compliance with these standards would ensure that additional water supply is made available. Increased water conservation and use of recycled water helps reduce reliance on imported water supplies, and reduces or delays the need for additional water facilities.

Water Conservation Act (SBX 7-7): Compliance with this act would help reduce water consumption by various users, including new urban development, and could thus make additional water (potentially up to 20%) available for use. Increased water conservation would help reduce reliance on imported water supplies and reduce or delay the need for additional water facilities.

b. Compliance with Existing Riverside County Regulations

Compliance with the following Riverside County regulations would prevent or reduce significant impacts due to the need for new or expanded water or wastewater treatment facilities. These regulations are already in effect in Riverside County and are not part of the project, GPA No. 960. Rather, these policies help ensure that potential environmental effects are avoided, reduced or minimized through their application on a case-by-case basis. The County of Riverside has existing programs in place that ensure applicable policies are imposed once a development proposal triggers a specific policy or policies. The need for specific policies is determined through subsequent site-specific CEQA analysis performed at the time of implementing project review. These measures are implemented, enforced and verified through their inclusion into project conditions of approval.

Ordinance No. 592 – Regulating Sewer Use, Sewer Construction and Industrial Wastewater Discharges in County Service Areas: This ordinance sets various standards for sewer use, construction and industrial wastewater discharges within Riverside County. As a result, Ordinance No. 592 serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 650 – Sewer Discharge in Unincorporated Territory: This ordinance prohibits the discharge of sewage and sewage effluent into any waterbodies above or below ground within Riverside County. It also

establishes a variety of regulations regarding sewer connections and OWTS. In this way, the ordinance protects water supplies, water and wastewater facilities and water quality.

Ordinance No. 682 – Construction, Reconstruction, Abandonment and Destruction of Wells: This ordinance establishes minimum standards for construction, reconstruction, abandonment and destruction of wells in order to protect underground water resources and provide safe water within Riverside County.

Ordinance No. 843 – Regulating the Discharge of Wastes into the Public Sewer System for the Highgrove Community: This ordinance regulates the discharge of wastes into the sewage collection systems of the Highgrove community and protects water supplies, water and wastewater facilities, and water quality for both surface water and groundwater.

c. Compliance with Existing General Plan Policies

Implementation of these water resource-related General Plan policies would reduce the effects of future development on water and wastewater facilities to less than significant. See Section 4.19.5.D for full text of each policy.

Policies OS 1.1 and 1.3: These policies address water supply issues at the county level and when considering projects for approval.

Policies OS 2.2 and 2.5: These policies address water conservation by encouraging the use of recycled water. Increased use of recycled water and water conservation reduces the need for imported water supplies and reduces or delays the need for additional infrastructure.

Policies OS 3.1-3.3: These policies address wastewater treatment and protection of water quality through compliance with various pollution discharge standards.

Policies LU 5.3, 21.2, 28.3, 29.7, 30.7, 31.4 and 32.6: These policies address project consistency with urban water management plans and require projects be reviewed to ensure water resources, including necessary infrastructure, are adequate for the proposed level of development.

d. Compliance with Proposed New or Revised General Plan Policies

The following proposed new or revised policies of the Riverside County General Plan would address potential impacts to water resources. See Section 4.19.5.D for full text of each of these policies.

Policies OS 1.4, 2.3 and 2.5: These policies address water conservation by encouraging the use of recycled water. Increased use of recycled water and water conservation reduces the need for imported water supplies and reduces or delays the need for additional infrastructure.

New Policies OS 2.1 and 18.1-18.6: These policies address water conservation through requirements for water-efficient landscaping. Decreasing irrigation water use means reducing the need for imported water supplies and reducing or delaying the need for additional infrastructure.

New Policy LU 22.2: This policy ensures water resources are adequate for the proposed level of development.

e. Compliance with Mitigation Measures from EIR No. 441

Existing Mitigation Measures 4.17.1 C and 4.17.1D, described previously under Impact 4.19.A, and Mitigation Measure 4.17.5A, described under Impact 4.19.E, would also aid in reducing impacts associated with the need for new or expanded water and wastewater facilities to less than significant.

3. Finding on Significance for Impact 4.19.G

With the implementation of the above-listed existing regulations, existing and proposed General Plan policies, existing mitigation measures from EIR No. 441, GPA No. 960 would have a less than significant impact on the environment due to the need for new or expanded water or wastewater facilities.

H. Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on- or off-site?

Impact 4.19.H – Substantially Alter Existing Drainage Patterns Resulting in Substantial Erosion or Siltation: Future development accommodated by the land use and policy changes proposed by the project, GPA No. 960, has the potential to increase water erosion, sedimentation and siltation of surface water. This includes short-term construction impacts, as well as long-term operational impacts. Future development also has the potential to threaten, damage or change hydrologic baseline conditions throughout Riverside County over time. However, compliance with existing laws, General Plan policies and existing EIR No. 441 mitigation measures, would be sufficient to ensure that this impact is less than significant.

1. Analysis of Impact 4.19.H

Future development in Riverside County accommodated by the project has the potential to increase erosion, sedimentation and siltation of surface water. This may occur due to the short-term disturbance of large quantities of earth during construction, as well as increased erosion potential in areas of new construction (i.e., due to vegetation removal, topsoil disturbance, etc.). This impact, however, would be held to less than significant levels as each new development in Riverside County would be required to adhere to existing regulations regarding construction practices that minimize risks of erosion and runoff. These regulations include adherence to applicable provisions of Riverside County Ordinance No. 754 (Stormwater/Urban Runoff Management and Discharge Controls), following best management practices (BMPs), obtaining and complying with the appropriate building permits, and obtaining and complying with NPDES permits.

BMPs consist of any activity, prohibition, practice, procedure, program, or other measure designed to prevent or reduce the discharge of pollutants directly or indirectly into waters of the United States. BMPs include, but are not limited to, those measures specified in the California Stormwater Best Management Practice Handbook for Municipal, Industrial/Commercial and Construction Activity, as well as those measures identified by the Director of the County of Riverside Transportation and Land Management Agency (TLMA). Typical BMPs include, but are not be limited to, the following:

- Revegetation of disturbed areas and planting of non-disturbed, but highly erosive, areas.
- Use of drought tolerant plants and irrigation systems which minimize runoff.

- Use of other erosion control devices such as rip-rap, gabions, concrete lining, small check dams, etc., to reduce erosion in gullies and active stream channels.
- Retention of onsite vegetation to the maximum extent possible.
- Limiting grading disturbance to the essential project area.
- Limiting grading activities during the rainy season.
- Balancing and limiting the amount of cut and fill to the extent possible.
- The diversion of water entering and exiting the site through the placement of interceptor trenches or other erosion control devices.
- Application of water or other soil stabilizer to disturbed areas to limit dust generation.
- Stabilization of soils at the construction entrance to reduce dirt tracked onto adjacent streets.
- Use of dikes, drains, swales or other features to divert and/or redirect runoff.

Post-construction runoff is also addressed and mitigated through site design and various requirements of State of California and County of Riverside programs, such as Riverside County's MS4 permit requirements for new development and substantial redevelopment, as well as standard Riverside County conditions of approval. These conditions include the requirement that projects not result in a net increase in water or runoff from the project site, that hydrology changes affecting Waters of the U.S. be made pursuant to CWA Section 404 permits and other similar measures.

Increased development resulting from implementation of the project would also reduce the distribution and extent of permeable surfaces suitable for recharge. It may also increase runoff and subsequent flow in streams, as well as increase the amount of non-point source pollutants that enter watercourses and recharge areas. Development activities may also result in the alteration or elimination features essential to local or regional hydrologic systems or interrupt hydrologic processes. Tables 4.19-BO and 4.19-BM show the approximate extent of known spatial areas that could be affected by future development accommodated by GPA No. 960. However, as noted previously, the mitigation measures outlined herein would ensure these impacts are reduced to less than significant levels.

2. Regulatory Compliance Affecting Impact 4.19.H

The adverse effects associated with potential changes to drainage patterns and hydrology, would be avoided, reduced or minimized through adherence to and compliance with the following regulations, policies and existing mitigation measures.

a. Compliance with Federal and State Regulations

Compliance with the following state and federal regulations would help reduce impacts due to changes to drainage patterns and hydrology.

Federal Water Pollution Control Act of 1972 (aka the Clean Water Act): As described above, compliance with this collection of federal regulations would ensure that changes to drainage patterns and hydrology do not adversely affect water quality, including through the discharge or causation of substantial erosion, siltation or sedimentation.

California Porter-Cologne Water Quality Control Act of 1970: As mentioned above, compliance with this collection of regulations would protect surface and groundwater sources from pollutant discharges, runoff and erosion, unpermitted hydrology disturbances and other activities that would adversely affect surface or groundwater.

b. Compliance with Existing Riverside County Regulations

Compliance with the following Riverside County regulations would prevent or reduce significant impacts to existing drainage patterns, erosion and siltation. These policies are already part of the General Plan and are not part of the project, GPA No. 960. Rather, they help ensure that potential environmental effects are avoided, reduced or minimized through the application of these policies on a case-by-case basis. The County of Riverside has existing programs in place that ensure applicable policies are imposed once a development proposal triggers a specific policy or policies. The need for specific policies is determined through subsequent site-specific CEQA analysis performed at the time of implementing project review. These measures are implemented, enforced and verified through their inclusion into project conditions of approval.

Ordinance No. 457 - Building Codes and Fees: This ordinance establishes the building and construction standards by which all development approved within unincorporated Riverside County must comply. This includes standards addressing erosion, runoff, drainage, flood control and water safety. In particular, it also includes requirements for preparation of a Storm Water Pollution Prevention Plan (SWPPP) for construction sites, implementation of year-round best management practices (BMPs) on such sites and the monitoring and maintaining of the BMPs to ensure they continue to provide adequate stormwater flow/runoff protections, erosion protection and sediment controls, both during and after construction activities on a site.

Ordinance No. 458 - Regulating Flood Hazard Areas and Implementing the National Flood Insurance Program: This ordinance enacts measures that ensure that water and wastewater systems are adequately protected from flooding and would not contaminate or be contaminated by floodwaters. Thus, Ordinance No. 458 serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 461 - Road Improvement Standards: This ordinance sets standards for roads, bridges and other transportation-related facilities, including those aspects of hydrology, flood control and associated drainage functions. It also serves to place to prevent significant adverse impacts due to road construction, runoff and stormwater flows from roadways, as well as water erosion.

Ordinance No. 659 – Development Mitigation Fee for Residential Development (DIF Program): This ordinance sets a range of development impact fees for new residential, commercial and industrial development to reduce impacts caused by such development. It mitigates growth impacts (particularly those arising from population growth) on public facilities. The provision of these facilities, including flood control facilities, ensures that hydrology changes would not result in impacts to hydrology or erosion due to lack of infrastructure.

Ordinance No. 754 - Stormwater/Urban Runoff Management and Discharge Controls: This ordinance protects the health, safety and general welfare of Riverside County residents by imposing restrictions to regulate discharges to stormdrain systems and reduce pollutants entering the storm drains. Among other things, the

ordinance requires that all discharge to storm drain systems be confined to stormwater runoff discharged pursuant to a NPDES permit and RWQCB authorization. The intent of this ordinance is to protect and enhance the water quality of county watercourses, water bodies, groundwater and wetlands pursuant to the federal CWA and the CWC, as well as other applicable state and federal regulations. By requiring specific standards for development and establishing a program for the approval, implementation and verification of such measures, Ordinance No. 754 mitigates impacts from stormwater flows and runoff, including flooding, erosion, sedimentation and siltation.

Ordinance No. 859 - Water-Efficient Landscape Requirements: This ordinance outlines water-efficient landscape standards for development within Riverside County per the California Water Conservation in Landscaping Act and other state regulations. It establishes standards related to planning, installing and maintaining landscaping and irrigation. By requiring reduced water use for landscape irrigation, Ordinance No. 859 protects existing water supplies (surface and groundwater). And by limiting water applications, it also helps minimize water runoff and water erosion in landscaped areas.

c. Compliance with Existing General Plan Policies

The following existing Riverside County General Plan policies would help reduce significant impacts to drainage patterns, erosion and siltation. See Section 4.19.5.D for full text of each policy.

Policies OS 2.2 and 2.5: These policies address water conservation by encouraging the use of recycled water. Increased use of recycled water and water conservation reduces the potential for excess water runoff that could cause or contribute to erosion, sedimentation or siltation.

Policies OS 3.1-3.3: These policies address wastewater treatment and protection of water quality through compliance with various pollution discharge standards.

Policies OS 4.4 and 4.8: These policies address protection of natural drainages which contribute to aquifer recharge and, hence, aid in protecting groundwater basins from draw-down.

Policies OS 6.1 and 6.3: These policies address protection of wetlands and other riparian resources from hydrological disruption, protection of water quality within floodplains and drainages, and minimization of erosion effects.

d. Compliance with Proposed New or Revised General Plan Policies

The following proposed new or revised policies of the Riverside County General Plan would address potential impacts on existing drainage patterns, erosion and siltation. See Section 4.19.5.D for full text of each of these policies.

Policies OS 1.4, 2.3 and 2.4: These policies address water conservation by encouraging the use of recycled water. Increased use of recycled water and water conservation reduces the need for imported water supplies and reduces or delays the need for additional infrastructure.

Policies OS 4.5 and 4.6: These policies address protection of natural drainages which contribute to aquifer recharge and, hence, aid in protecting groundwater basins from draw-down. In particular, policy OS 4.6 addresses the retention of stormwater runoff within a development site in order to both prevent erosion offsite and facilitate groundwater recharge onsite.

New Policies OS 2.1 and 18.1-18.6: These policies address water conservation through requirements for water-efficient landscaping. Decreasing irrigation water use would prevent erosion, siltation and sedimentation both onsite and off.

New Policies OS 3.4-3.7: These policies address requirements to comply with NPDES and other regulations addressing pollution discharges and runoff to protect stormwater quality and, ultimately surface and groundwater fed by stormwater runoff.

Policies LU 9.1, 9.2 and 9.4: These policies address protection of wetlands and other riparian resources from hydrological disruption, protection of water quality within floodplains and drainages, and minimization of erosion effects.

e. Compliance with Mitigation Measures from EIR No. 441

In addition to the below specific mitigation measures from EIR No. 441 that address drainage patterns and erosion directly, existing Mitigation Measures 4.17.5B and 4.17.5D (see Impact 4.19.D), 4.17.5E (Impact 4.19.I) and 4.9.1D (Impact 4.19.J), would also aid in reducing impacts on existing drainage patterns, erosion and siltation.

Existing Mitigation Measure 4.17.4A Where development may interfere with, disrupt, or otherwise affect surface or subsurface hydrologic baseline conditions (as determined by the Riverside County Flood Control and Water Conservation District, the United States Army Corps of Engineers, the California Department of Fish and Wildlife, and/or the Regional Water Quality Control Board), preparation of a project specific hydrologic study shall be required. The hydrologic study shall include (but shall not be limited to): an inventory of surface and subsurface hydrologic conditions existing at the time of the study; an analysis of how the proposed development would affect these hydrologic baseline conditions; and specific measures to limit or eliminate the interference or disruption of the onsite hydrologic process. The hydrologic study shall evaluate the feasibility of incorporating bioengineering measures into any project that may alter the hydrologic process. Where required by the County [of Riverside], the hydrologic study shall include analysis of, at an equal level of detail, potential impacts to tributary or downstream areas. The hydrologic study shall be submitted to the County [of Riverside] or responsible entity for review and shall be approved prior to the issuance of any entitlement that would result in the physical modification of the project site.

Existing Mitigation Measure 4.17.4B: The project applicant shall submit to the County [of Riverside] for review and approval, evidence that the specific measures to limit or eliminate the disruption or interference to the hydrologic process resulting from the entire development process, will be implemented as set forth in the hydrologic study. Such evidence may take the form of (but shall not be limited to): a development agreement; land banking; the provision of adequate funds to guarantee the construction, maintenance or restoration of hydrologic features; or any other mechanism that will achieve said goals. Said evidence shall be submitted and approved prior to the issuance of any entitlement that would result in the physical modification of the project site.

Existing Mitigation Measure 4.17.4C: Where determined feasible by the County [of Riverside] or responsible entity, bioengineering measures shall be incorporated into any project that may alter the hydrologic process.

Existing Mitigation Measure 4.9.1C: Riverside County shall not necessarily require all land uses to withstand flooding. These may include land uses such as agricultural, golf courses, and trails. For these land uses, flows shall not be obstructed, and upstream and downstream properties shall not be adversely affected by increased velocities, erosion backwater effects, concentration of flows, and adverse impacts to water quality from point and nonpoint sources of pollution.

Existing Mitigation Measure 4.9.2C: Riverside County shall require that for agricultural, recreation or other low-density uses, flows are not obstructed and that upstream and downstream properties are not adversely affected by increased velocities, erosion backwater effects or concentration of flows.

Existing Mitigation Measure 4.10.9A: Riverside County, where required, and in accordance with issuance of a National Pollutant Discharge Elimination System (NPDES) permit, shall require the construction and/or grading contractor for individual developments to establish and implement specific Best Management Practices (BMPs) at time of project implementation.

Existing Mitigation Measure 4.10.9B: Prior to any development within the County [of Riverside], a grading plan shall be submitted to the Riverside County Building and Safety Department and/or Riverside County Geologist for review and approval. As required by the County [of Riverside], the grading plan shall include erosion and sediment control plans. Measures included in individual erosion control plans may include, but shall not be limited to, the following:

- Grading and development plans shall be designed in a manner which minimizes the amount of terrain modification.
- Surface water shall be controlled and diverted around potential landslide areas to prevent erosion and saturation of slopes.
- Structures shall not be sited on or below identified landslides unless slides are stabilized.
- The extent and duration of ground disturbing activities during and immediately following periods of rain shall be limited, to avoid the potential for erosion which may be accelerated by rainfall on exposed soils.
- To the extent possible, the amount of cut and fill shall be balanced.
- The amount of water entering and exiting a graded site shall be limited though placement of interceptor trenches or other erosion control devices.
- Erosion and sediment control plans shall be submitted to the County [of Riverside] for review and approval prior to the issuance of grading permits.

Existing Mitigation Measure 4.10.9C: Where required, drainage design measures shall be incorporated into the final design of individual projects onsite. These measures shall include, but will not be limited to:

- Runoff entering developing areas shall be collected into surface and subsurface drains for removal to nearby drainages.
- Runoff generated above steep slopes or poorly vegetated areas shall be captured and conveyed to nearby drainages.
- Runoff generated on paved or covered areas shall be conveyed via swales and drains to natural drainage courses.
- Disturbed areas that have been identified as highly erosive shall be (re)vegetated.
- Irrigation systems shall be designed, installed and maintained in a manner which minimizes runoff.

- The landscape scheme for projects within the project site shall utilize drought-tolerant plants.
- Erosion control devices such as rip-rap, gabions, small check dams, etc., may be utilized in gullies and active stream channels to reduce erosion.

3. Finding on Significance for Impact 4.19.H

With the implementation of the above regulations, ordinances, existing and proposed General Plan policies and existing mitigation measures from EIR No. 441, future development accommodated by GPA No. 960 would have a less than significant impact on existing drainage patterns, erosion, sedimentation and siltation

I. Would the project create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff?

Impact 4.19.I – Cause Runoff Exceeding Stormwater Drainage System Capacity or Cause Substantial Water Pollution: Future development accommodated by the land use and policy changes proposed by the project, GPA No. 960, would result in the development of vacant lands within Riverside County. The addition of impervious surfaces from this development would increase stormwater runoff throughout Riverside County. In some areas, existing drainage facilities may not be adequate to accommodate the increase. However, compliance with existing laws, regulatory programs, ordinances, General Plan policies and existing mitigation measures from EIR No. 441, would be sufficient to ensure that this impact is less than significant.

1. Analysis of Impact 4.19.I

Future development accommodated by the project in presently vacant unincorporated areas of Riverside County would result in an increase in residential and non-residential structures and associated facilities (e.g., roads), increasing the amount of unincorporated land covered in impermeable surfaces, thereby limiting the amount of ground infiltration during storm events. The passage of storm flows over impermeable surfaces would increase the volume and rate of storm runoff. Roads and buildings generate greater amounts of runoff than typical vegetated land. Fixed drainage channels in urban areas may be unable to contain the runoff generated by relatively small, but intense rainfall events that are known to occur in Riverside County, particularly in the San Jacinto Mountains and eastern desert regions. Table 4.19-BM shows the acreages for areas of known spatial changes associated with GPA No. 960. At minimum, hydrological disturbances would occur in these areas with future implementation of these project changes.

When development is introduced into an area, it creates the potential for urban runoff, which can be a major contributor of non-point source water pollution. (Urban runoff can carry pollutants, including those from: operation of internal combustion engines, atmospheric deposition, brake pad and tire wear, pesticide residues, nutrient (fertilizer) runoff from landscaping and agricultural activities, as well as leaching of naturally occurring minerals from local geology.) When it rains, the impervious surfaces associated with developed areas (roads, parking lots, sidewalks, roofs, etc.) carry polluted stormwater to storm drains, which eventually discharge to surface waters like rivers and streams. In many cases the water in these storm drain systems is discharged without any kind of water quality treatment. Fertilizers used on residential lawns, parks and golf courses are a major source of nitrates and phosphorus in urban runoff.

With the increase in stormwater runoff caused by new land uses, there would be the potential for an increase in pollutants conveyed to the groundwater basins and surface waters in creeks and rivers. Effective control of urban

runoff involves reducing the velocity and volume of stormwater flows leaving a site, as well as decreasing pollutants in these flows. A variety of stormwater management practices and systems can be used to lower the effects of urban runoff. Runoff management systems can include infiltration basins, bioretention systems (e.g., reeds and other riparian vegetation which filter the runoff, improving water quality), constructed wetlands, retention basins, etc. Compliance with a variety of BMPs are required as part of the Riverside County-issued conditions of approval for new development projects.

Thus, project effects on runoff are not considered significant for a combination of several reasons. First, the extensive stormwater management measures required of all new development would reduce urban runoff impacts. Secondly, these impacts would occur incrementally as the result of many individual implementing projects scattered across Riverside County and spread over the 50-year build out. Lastly, stormwater management regulations require developments to ensure that no net increase in water flows leaving a site, further minimizing runoff and its impacts to storm drain systems.

2. Regulatory Compliance Affecting Impact 4.19.I

The adverse effects associated with potential effects of runoff on stormdrain systems and pollution levels would be avoided, reduced or minimized through adherence to and compliance with the following regulations, policies and existing mitigation measures.

a. Compliance with Federal and State Regulations

Compliance with the following state and federal regulations would help reduce impacts due to stormwater flows, runoff and pollution associated with them.

Federal Water Pollution Control Act of 1972 (aka the Clean Water Act): As described above, compliance with this collection of federal regulations would ensure that all changes in drainage patterns and hydrology do not adversely affect water quality, including through the discharge or causation of runoff or pollutants.

CWA Section 402 – National Pollutant Discharge Elimination System: The CWA's NPDES permit program focuses on discharges from municipal wastewater plants, but also applies to industrial discharges, construction site dewatering discharges and stormwater discharges to surface waters. Municipalities, publicly owned treatment works and most industries in the U.S. are required to obtain an NPDES permit for discharges, including stormwater runoff. NPDES permits regulate discharge of "pollutants from point sources to waters of the United States" to protect surface water quality and their beneficial use. The responsibility for issuing NPDES permits in California has been delegated to the RWQCBs – three of which have jurisdiction in Riverside County. See Section 4.19.2.E for full details.

California Porter-Cologne Water Quality Control Act of 1970: As mentioned above, compliance with this collection of regulations would protect surface and groundwater sources from pollutant discharges, runoff and erosion, unpermitted hydrology disturbances and other activities that would adversely affect storm drain systems and surface water quality.

b. Compliance with Existing Riverside County Regulations

Compliance with the following Riverside County regulations would prevent or reduce significant impacts due to stormwater runoff and associated water pollution. These regulations are already in effect in Riverside County and are not part of the project, GPA No. 960. Rather, these policies help ensure potential environmental effects are

avoided, reduced or minimized through their application on a case-by-case basis. The County of Riverside has existing programs in place that ensure applicable policies are imposed once a development proposal triggers a specific policy or policies. The need for specific policies is determined through subsequent site-specific CEQA analysis performed at the time of implementing project review. These measures are implemented, enforced and verified through their inclusion into project conditions of approval.

Ordinance No. 457 - Building Codes and Fees: This ordinance specifies the various building and construction standards to which all development approved within unincorporated Riverside County must comply. These codes ensure that all development and construction in Riverside County meets necessary standards, including for erosion, runoff, drainage and flood control. It also includes requirements for preparation of a Storm Water Pollution Prevention Plan (SWPPP) for construction sites, implementation of year-round best management practices (BMPs) on such sites and the monitoring and maintaining of the BMPs to ensure they provide adequate stormwater flow/runoff protections, erosion protection and sediment control, both during and after construction activities. As a result, compliance with this ordinance ensures adequate measures are in place to prevent significant adverse impacts due to construction and urban runoff, stormwater flows and water erosion on lands subject to development.

Ordinance No. 461 - Road Improvement Standards: While not addressing water resources directly, this ordinance does set forth standards for roads, bridges and other transportation-related facilities, including those aspects of hydrology, flood control and associated drainage functions. Ordinance No. 461 serves to mitigate potential flooding hazards to people, property and structures by ensuring that roads and associated improvements and features are designed, constructed and maintained in a manner appropriate to the water flow and flooding hazard potential. It also serves to place to prevent significant adverse impacts due to road construction, runoff and stormwater flows from roadways, as well as water erosion.

Ordinance No. 592 – Regulating Sewer Use, Sewer Construction and Industrial Wastewater Discharges in County Service Areas: This ordinance sets various standards for sewer use, construction and industrial wastewater discharges within Riverside County to protect both water quality and the infrastructure conveying and treating these wastewaters. As a result, Ordinance No. 592 protects water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 650 – Sewer Discharge in Unincorporated Territory: This ordinance prohibits the discharge of sewage and sewage effluent into any waterbodies above or below ground within Riverside County. It also establishes a variety of regulations regarding sewer connections and OWTS. In this way, Ordinance No. 650 protects water supplies, water and wastewater facilities and water quality.

Ordinance No. 659 – Development Mitigation Fee for Residential Development (DIF Program): This ordinance sets a range of development impact fees for new residential, commercial and industrial development to reduce impacts caused by such development. It mitigates growth impacts (particularly those arising from population growth) on public facilities. For flood control and storm drain facilities, in the areas in which flood control fees have been authorized, the DIF program ensures fees are collected and expended to provide necessary facilities commensurate with the ongoing levels of development. The provision of these facilities ensures that future new development would not result in runoff exceeding stormwater drainage systems nor cause substantial additional sources of polluted runoff.

Ordinance No. 754 - Stormwater/Urban Runoff Management and Discharge Controls: This ordinance protects the health, safety and general welfare of Riverside County residents by imposing restrictions to regulate discharges to stormdrain systems and reduce pollutants entering the storm drains (and, ultimately, surface and groundwater within Riverside County). Among other things, the ordinance requires that all discharge to storm

drain systems be confined to stormwater runoff discharged pursuant to a NPDES permit and RWQCB authorization. The intent of this ordinance is to protect and enhance the water quality of county watercourses, water bodies, groundwater and wetlands pursuant to the federal CWA and the CWC, as well as other applicable state and federal regulations. By requiring specific standards for development and establishing a program for the approval, implementation and verification of such measures, Ordinance No. 754 mitigates potential hazards that could arise from stormwater flows and runoff, including flooding and erosion, and its effects on water quality and water infrastructure.

Ordinance No. 843 – Regulating the Discharge of Wastes into the Public Sewer System for the Highgrove Community: This ordinance regulates the discharge of wastes into the sewage collection systems of the Highgrove community and protects water supplies, water and wastewater facilities, and water quality for both surface water and groundwater.

Ordinance No. 859 - Water-Efficient Landscape Requirements: This ordinance establishes a number of water-efficiency standards related to the planning, installation and maintenance of landscaping and irrigation. By requiring a reduction in the amount of water used for landscape irrigation, Ordinance No. 859 helps minimize water runoff and water erosion in landscaped areas.

c. Compliance with Existing General Plan Policies

The following existing policies of the Riverside County General Plan would help reduce significant impacts due to runoff and associated pollution. See Section 4.19.5.D for full text of each policy.

Policies OS 2.2 and 2.5: These policies address water conservation by encouraging the use of recycled water. Increased use of recycled water and water conservation reduces the need for imported water supplies and reduce potential for runoff.

Policies OS 3.1-3.3: These policies address wastewater treatment and protection of water quality through compliance with various pollution discharge standards.

Policies OS 4.4 and 4.8: These policies address protection of natural drainages which contribute to aquifer recharge and, hence, aid in protecting groundwater basins from draw-down.

Policies OS 6.1, 6.3 and LU 9.2: These policies address protection of wetlands and other riparian resources from hydrological disruption, protect water quality within floodplains and drainages, and minimize erosion effects.

Policies LU 5.3, 21.2, 22.2, 28.3, 29.7, 30.7, 31.4 and 32.6: These policies address project consistency with urban water management plans and require projects be reviewed to ensure water resources are adequate for the proposed level of development.

d. Compliance with Proposed New or Revised General Plan Policies

The following proposed new or revised policies of the Riverside County General Plan would address potential impacts to runoff and associated pollution. See Section 4.19.5.D for full text of each of these.

Policies OS 1.4, 2.3 and 2.4: These policies address water conservation by encouraging the use of recycled water. Increased use of recycled water and water conservation reduces the need for imported water supplies and reduce potential for runoff.

New Policies OS 2.1 and 18.1-18.6: These policies address water conservation through requirements for water-efficient landscaping. Decreasing irrigation water use means a reduced need for imported water supplies and reduced potential for runoff and associated pollutants.

New Policies OS 3.4-3.7: These policies address requirements to comply with NPDES and other regulations addressing pollution discharges and runoff to protect stormwater quality and, ultimately surface and groundwater fed by stormwater runoff.

Policies OS 4.5 and 4.6: These policies address protection of natural drainages which contribute to aquifer recharge and, hence, aid in protecting groundwater basins from draw-down. In particular, Policy OS 4.6 addresses the retention of stormwater runoff within a development site in order to both prevent erosion offsite and facilitate groundwater recharge onsite.

Policies LU 9.1 and 9.4: These policies address protection of wetlands and other riparian resources from hydrological disruption, protection of water quality within floodplains and drainages, and minimization of erosion effects.

New Policy LU 22.2: This policy ensures water resources are adequate for the proposed level of development.

e. Compliance with Mitigation Measures from EIR No. 441

In addition to the below specific mitigation measures from EIR No. 441 that address runoff issues directly, existing Mitigation Measures 4.9.2C, 4.10.9A, 4.10.9B and 4.10.9C (see Impact 4.19.H) and Mitigation Measure 4.17.5B (see Impact 4.19.D), would also aid in reducing impacts due to runoff.

Existing Mitigation Measure 4.17.5E: For each new development project, the following principles and policies shall be considered and implemented:

a. Avoid or limit disturbance to natural water bodies and drainage systems (including ephemeral drainage systems) when feasible. Provide adequate buffers of native vegetation along drainage systems to lessen erosion and protect water quality.

b. Appropriate best management practices (BMPs) must be implemented to lessen impacts to waters of the United States and/or waters of the State of California resulting from development. Drainages should be left in a natural condition or modified in a way that preserves all existing water quality standards where feasible. Any discharges of sediment or other wastes, including wastewater, to Waters of the United States or Waters of the State must be avoided to the maximum extent practicable. All such discharges will require an NPDES permit issued by the Regional Water Quality Control Board (RWQCB).

c. Small drainages shall be preserved and incorporated into new development, along with adequate buffer zones of native vegetation, to the maximum extent practicable.

d. Any impacts to waters of the United States require a Section 401 Water Quality Standards Certification from the RWQCB. Impacts to these waters shall be avoided to the maximum extent practicable. Where avoidance is not practicable, impacts to these waters shall be minimized to the maximum extent

practicable. Mitigation of unavoidable impacts must, at a minimum, replace the full function and value of the affected water body. Impacts to waters of the United States also require a Clean Water Act Section 404 Permit from the United States Army Corps of Engineers and a Streambed Alteration Agreement from the California Department of Fish and Wildlife.

e. The County [of Riverside] shall encourage the use of pervious materials in development to retain absorption and allow more percolation of stormwater into the ground. The use of pervious materials, such as grass, permeable/porous pavement, etc., for runoff channels and parking areas shall also be encouraged. Lining runoff channels with impermeable surfaces, such as concrete or grouted riprap, will be discouraged.

f. The County [of Riverside] shall encourage construction of detention basins or holding ponds and/or constructed wetlands within a project site to capture and treat dry weather urban runoff and the first flush of rainfall runoff. These basins should be designed to detain runoff for a minimum time, such as 24 hours, to allow particles and associated pollutants to settle and to provide for natural treatment.

g. The County [of Riverside] shall encourage development to retain areas of open space as natural or landscaped to aid in the recharge and retention of runoff. Native plant materials shall be used in replanting and hydroseeding operations, where feasible.

h. The County [of Riverside] shall require that environmental documents for proposed projects in areas tributary to Canyon Lake Reservoir, Lake Elsinore, sections of the Santa Ana River, Fulmar Lake, and Mill Creek (as a result of the proposed 2002 303 (d) listing of these waterbodies) include discharge prohibitions, revisions to discharge permits, or management plans to address water quality impacts in accordance with the controls that may be applied pursuant to state and federal regulation. Environmental documents shall acknowledge that additional requirements may be imposed in the future for projects in areas tributary to the water bodies listed above.

i. The County [of Riverside] shall ensure that in new development, post-development stormwater runoff flow rates do not differ from the pre-development stormwater runoff flow rates.

j. All construction projects should be designed and implemented to protect, and if at all possible, to improve the quality of the underlying groundwater.

k. The County [of Riverside] shall encourage the enhancement of groundwater recharge wherever possible. Measures such as keeping stream/river channels and floodplains in natural conditions or with pervious surfaces, as well as keeping areas of high recharge as open space will be considered.

l. The County [of Riverside] shall prohibit the discharge of waste material resulting from any type of construction into any drainage areas, channels, streambeds, streams, lakes, wetlands or rivers. Spoil sites shall be prohibited within any streams or areas where spoil material could be washed into a water body.

m. The County [of Riverside] shall require that appropriate BMPs be developed and implemented during construction efforts to control the discharge of pollutants, prevent sewage spills, and to avoid discharge of sediments into the streets, stormwater conveyance channels or waterways.

Existing Mitigation Measure 4.9.1.D: Riverside County shall require the 10-year flood flows to be contained within the top of curbs and the 100-year flood flows within the street rights-of-way.

3. Finding on Significance for Impact 4.19.I

Implementation of the above regulations, ordinances, General Plan policies and existing mitigation measures from EIR No. 441, would reduce runoff resulting from implementation of future development accommodated by the project and ensure runoff waters meet applicable water quality standards. As a result, GPA No. 960 would have a less than significant impact on the capacity of storm drain systems due to generation of runoff and would not cause substantial additional sources of polluted runoff.

J. Would the project require or result in the construction of new stormwater drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?

Impact 4.19.J – Cause Significant Adverse Effects Due to the Need for New or Expanded Stormwater Drainage Facilities: Future development accommodated by the land use and policy changes proposed by the project, GPA No. 960, would result in the development of vacant lands within Riverside County. The addition of impervious surfaces would increase the potential stormwater runoff from areas throughout Riverside County. Existing drainage facilities may not be adequate to accommodate the future potential increase in stormwater runoff. As a result, additional storm drain capacity and facilities may be necessary. It is feasible, however, for such future facilities to be planned, sited and constructed in a manner that minimizes potential environmental effects. In addition, compliance with existing laws, regulatory programs, ordinances, General Plan policies and existing mitigation measures from EIR No. 441, would be sufficient to ensure that this impact is less than significant.

1. Analysis of Impact 4.19.J

As described under Impact 4.19.I, above, future development accommodated by GPA No. 960 would result in increased stormwater and urban runoff due mainly to increases in the amount of impervious surfaces. These effects, however, are not considered significant because they would occur incrementally as the result of many individual implementing projects scattered across Riverside County and spread over the roughly 50-year build out period. Further, it is expected that such future facilities would be planned, sited and constructed in a manner that minimizes potential environmental effects.

2. Regulatory Compliance Affecting Impact 4.19.J

The adverse effects associated with potential need for new or expanded stormdrain facilities would be avoided, reduced or minimized through adherence to and compliance with the following regulations, policies and existing mitigation measures.

a. Compliance with Federal and State Regulations

Compliance with the following state and federal regulations would help reduce impacts due to the need for new or expanded stormdrain facilities.

Federal Water Pollution Control Act of 1972 (aka the Clean Water Act): As described above, compliance with this collection of federal regulations would ensure that all changes in drainage patterns and hydrology do not adversely affect water quality, including through the discharge or causation of runoff or pollutants.

California Porter-Cologne Water Quality Control Act of 1970: As mentioned above, compliance with this collection of regulations would protect surface and groundwater sources from pollutant discharges, runoff and erosion, unpermitted hydrology disturbances and other activities that would adversely affect storm drain systems and surface water quality.

b. Compliance with Existing Riverside County Regulations

Compliance with the following Riverside County regulations would prevent or reduce significant impacts due to the need for new or expanded storm drain facilities. These regulations are already in effect in Riverside County and are not part of the project, GPA No. 960. Rather, these policies help ensure that potential environmental effects are avoided, reduced or minimized through their application on a case-by-case basis. The County of Riverside has existing programs in place that ensure applicable policies are imposed once a development proposal triggers a specific policy or policies. The need for specific policies is determined through subsequent site-specific CEQA analysis performed at the time of implementing project review. These measures are implemented, enforced and verified through their inclusion into project conditions of approval.

Ordinance No. 457 - Building Codes and Fees: This ordinance establishes the building and construction standards by which all development approved within unincorporated Riverside County must comply. This includes standards addressing erosion, runoff, drainage, flood control and water safety. In particular, it also includes requirements for preparation of a Storm Water Pollution Prevention Plan (SWPPP) for construction sites, implementation of year-round best management practices (BMPs) on such sites and the monitoring and maintaining of the BMPs to ensure they continue to provide adequate stormwater flow/runoff protections, erosion protection and sediment controls, both during and after construction activities on a site.

Ordinance No. 458 - Regulating Flood Hazard Areas and Implementing the National Flood Insurance Program: This ordinance enacts measures that ensure that water and wastewater systems are adequately protected from flooding and would not contaminate or be contaminated by floodwaters. Thus, Ordinance No. 458 serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 461 - Road Improvement Standards: This ordinance sets standards for roads, bridges and other transportation-related facilities, including those aspects of hydrology, flood control and associated drainage functions to prevent significant adverse impacts due to road construction, runoff and stormwater flows from roadways, as well as water erosion.

Ordinance No. 592 – Regulating Sewer Use, Sewer Construction and Industrial Wastewater Discharges in County Service Areas: This ordinance sets various standards for sewer use, construction and industrial wastewater discharges within Riverside County. As a result, Ordinance No. 592 serves to protect water supplies, water and wastewater facilities and water quality for both surface water and groundwater.

Ordinance No. 650 – Sewer Discharge in Unincorporated Territory: This ordinance prohibits the discharge of sewage and sewage effluent into any waterbodies above or below ground within Riverside County. It also establishes regulations regarding sewer connections and OWTS. In this way, Ordinance No. 650 protects water supplies, water and wastewater facilities and water quality.

Ordinance No. 659 – Development Mitigation Fee for Residential Development (DIF Program): This ordinance sets a range of development impact fees to be used "in order to effectively implement the Riverside County General Plan, manage new residential, commercial and industrial development and reduce impacts caused by such development." It mitigates growth impacts (particularly those arising from population growth) on public

facilities within Riverside County to ensure residents are not placed into conditions perilous to their health, safety, comfort or welfare. To accomplish this, fees are assessed on the basis of regional location within Riverside County, land use type (per dwelling unit for residential units and per acre for all other uses) and the applicable categories of facilities to be provided. For flood control facilities, the DIF program ensures fees are collected and expended to provide necessary facilities commensurate with the ongoing levels of development in specific areas not already subject to, or in addition to, Area Drainage Plan fees as under Ordinance No. 458. Thus, Ordinance No. 659 mitigates development impacts on stormdrain and flood control facilities and future needs for these by ensuring that funds are collected and utilized to provide needed facilities as development progresses within Riverside County. The provision of these facilities ensures new development does not expose people, property or structures to undue risks from drainage or stormwater flows.

Ordinance No. 754 - Stormwater/Urban Runoff Management and Discharge Controls: This ordinance protects the health, safety and general welfare of Riverside County residents by imposing restrictions to regulate discharges to stormdrain systems, including requiring all discharge to stormdrain systems be pursuant to NPDES permit and RWQCB authorization. By requiring specific standards for development and establishing a program for the approval, implementation and verification of such measures, Ordinance No. 754 mitigates potential hazards that could arise from stormwater flows and runoff, including flooding and erosion, and its effects on water quality and water infrastructure.

Ordinance No. 843 – Regulating the Discharge of Wastes into the Public Sewer System for the Highgrove Community: This ordinance regulates the discharge of wastes into the sewage collection systems of the Highgrove community and protects water supplies, water and wastewater facilities, and water quality for both surface water and groundwater.

c. Compliance with Existing General Plan Policies

The following existing policies of the Riverside County General Plan would help reduce significant impacts due to the need for new or expanded stormwater drainage facilities. See Section 4.19.5.D for full text of each of these policies.

Policies OS 6.1, 6.3; LU 9.2 and 9.3: These policies address protection of wetlands and other riparian resources from hydrological disruption, protect water quality within floodplains and drainages, and minimize erosion effects.

d. Compliance with Proposed New or Revised General Plan Policies

The following proposed new or revised policies of the Riverside County General Plan would address potential impacts to water resources. See Section 4.19.5.D for full text of each of these policies.

New Policies OS 2.1 and 18.1-18.6: These policies address water conservation through requirements for water-efficient landscaping. Decreasing irrigation water use means reducing the need for imported water supplies and decreasing draw-down of local groundwater basins.

New Policies OS 3.4-3.7: These policies address requirements to comply with NPDES and other regulations addressing pollution discharges and runoff to protect stormwater quality and, ultimately surface and groundwater fed by stormwater runoff.

Policies LU 9.1 and 9.4: These policies address protection of wetlands and other riparian resources from hydrological disruption, protect water quality within floodplains and drainages, and minimize erosion effects.

e. Compliance with Mitigation Measures from EIR No. 441

In addition to the specific mitigation measure below from EIR No. 441 that addresses stormwater flows directly, Mitigation Measures 4.17.5D (see Impact 4.19.D), 4.17.5E (Impact 4.19.I) and 4.10.9A, 4.10.9B, 4.10.9C, 4.17.4A, 4.17.4B and 4.17.4C (Impact 4.19.H) would also aid in reducing impacts due to the need for new or expanded storm drain facilities.

Existing Mitigation Measure 4.9.1.D: Riverside County shall require the 10-year flood flows to be contained within the top of curbs and the 100-year flood flows within the street rights-of-way.

3. Finding on Significance for Impact 4.19.J

With the implementation of the above-listed existing regulations, ordinances, existing and proposed General Plan policies, existing mitigation measures from EIR No. 441, GPA No. 960 would have a less than significant impact due to the need for new or expanded stormwater drainage facilities as a result of future development accommodated by the project over the next 50 or so years.

4.19.9 Water Resources – Significance After Mitigation

Implementation of and compliance with the above regulations, Riverside County General Plan policies, ordinances and existing mitigation measures from EIR No. 441 would ensure that significant impacts to or resulting from a variety of water resource issues would be either avoided or minimized to less than significant. This includes water quality degradation, violation of any water quality standards or waste discharge requirements, exceedance of any RWQCB wastewater treatment requirements, exceedance of existing or planned wastewater treatment capacity, impacts due to the need for new or expanded water, wastewater or stormwater drainage facilities, alteration of existing drainage patterns and associated erosions and siltation, as well as runoff water exceeding existing or planned stormwater drainage systems and associated pollutants. While adherence to the stated policies in the proposed General Plan and mitigation in the EIR would reduce the above potential impacts to less than significant, in absence of project-specific water supply data, potential water supply impacts (including groundwater) – that is, Impacts 4.19.A and 4.19.B, resulting from future development accommodated by the project must be considered significant and unavoidable.

Additional Required CEQA Topics

Section 5.0
Additional Required CEQA Topics

5.0 About This Section

The following subsections of this chapter address significant environmental effects that cannot be avoided, significant irreversible environmental effects, effects on humans, growth-inducing impacts and cumulative impacts that would result if the proposed project, General Plan Amendment (GPA) No. 960, were implemented as part of build out of the Riverside County General Plan over time. In Section 5.6 the consistency of the General Plan, as it would be updated pursuant to GPA No. 960, is compared with various regional plans.

Different parts of GPA No. 960 affect various areas across and throughout Riverside County and some, such as the new greenhouse gas policies proposed for the General Plan Air Quality Element, span the entire county. As such, the scope of Section 5.0 generally encompasses all of unincorporated Riverside County. As would be expected, Sections 5.1, 5.2, 5.3 and 5.4 discuss the specific effects of the proposed changes included in GPA No. 960 in terms of unavoidable significant effects (Section 5.1), significant irreversible changes (Section 5.2), substantial human effects (Section 5.3) and growth-inducing effects (Section 5.4). For Section 5.5 (Cumulative Impacts) and Section 5.6 (Regional Consistency), however, the scope of analysis is broadened to address full build out of the Riverside County General Plan in its entirety. For example, this means that the effects of build out of the updated General Plan, reflecting the changes that would occur to the document if GPA No. 960 is approved, are compared to the effects projected for various other build out scenarios (existing General Plan without the project, cumulative projects, etc.). This distinction is necessary because the widespread nature of the various components of GPA No. 960 makes appropriate an examination of the end point at which all of these components would be realized.

It should also be noted that, with respect to CEQA, pursuant to Public Resources Code (PRC) Section 21081, where a significant impact has been identified in the EIR, the County of Riverside shall not approve or carry out the project unless the County of Riverside makes one or more of the following findings with respect to each significant effect:

1. Changes or alterations have been required in, or incorporated into, the project which mitigate or avoid the significant effects on the environment.

2. Those changes or alterations are within the responsibility and jurisdiction of another public agency and have been, or can and should be, adopted by that other agency.

3. Specific economic, legal, social, technological or other considerations, including considerations for the provision of employment opportunities for highly-trained workers, make infeasible the mitigation measures or alternatives identified in the environmental impact report.

In addition, pursuant to CEQA (PRC Section 21081.5), these findings must be based on substantial evidence in the record. The two tables below summarize all of the significant effects associated with GPA No. 960. Table 5.0-A (Unavoidable Significant Environmental Effects) outlines the effects found to be "significant" with respect to the criteria of CEQA, PRC Section 21083(b) and also significant effects found to be "unavoidable" per CCR Section 15126(b). These findings are discussed in full in Sections 5.1, 5.3 and 5.5. In addition, see the associated parts of Section 4.0 for the environmental baselines and analyses performed for the various impacts listed. Table 5.0-B (Summary of Significant Irreversible Changes and Growth-Inducing Effects) outlines the significant irreversible changes and growth-inducing effects associated with GPA No. 960. These findings are discussed in Sections 5.2 and 5.4.

Table 5.0-A: Unavoidable Significant Environmental Effects

Impact	Impact Title / Description[1]	Degrade Environment	Curtail Environment	Short-term Effects	Human Effects	Cumulative
4.3 – Population and Housing						
4.3.A	Induce direct or indirect population growth.					•
4.4 – Aesthetic and Visual Resources						
4.4.A	Adversely affect scenic vistas.					•
4.4.B	Adversely affect scenic resources within State Scenic Highways.					•
4.4.D	Cause adverse light and glare effects.					•
4.5 – Agricultural and Forestry Resources						
4.5.A	Cause the conversion of designated Farmlands.		•			•
4.5.B	Encroach on or conflict with existing agricultural uses.	•				•
4.6 – Air Quality						
4.6.A	Conflict with air quality plans.					•
4.6.B (1)	Cause significant construction (short-term) air emissions.	•			•	•
4.6.B (2)	Cause significant operational (long-term) air emissions.	•			•	•
4.6.C	Cause cumulatively significant project air quality impacts.	•			•	•
4.6.D	Expose sensitive receptors to air pollutants.	•			•	•
4.7 – Greenhouse Gases						
4.7.A	Generate greenhouse gas emissions, either directly or indirectly, that would cause or contribute to a substantial adverse physical effect on the environment.					•
4.7.B	Conflict with plans, policies or regulations for reducing greenhouse gas emissions.					•
4.9 – Cultural and Paleontological Resources						
4.9.B	Cause the destruction of known archeological resources.					•
4.9.C	Cause the destruction of unique paleontological resources or sites.					•
4.10 – Energy Resources						
4.10.A	Increase demand for electricity.					•
4.10.B	Increase demand for natural gas.					•
4.12 – Geology and Soils						
4.12.B	Expose people or structures to strong seismic groundshaking.				•	•
4.12.D	Expose people or structures to landslides.				•	•
4.13 – Hazardous Materials and Safety						
4.13.H	Expose people or structures to wildland fires.				•	•

Impact	Impact Title / Description[1]	Degrade Environment	Curtail Environment	Short-term Effects	Human Effects	Cumulative
4.15 – Noise						
4.15.A	Generate noise or cause noise exposure in excess of standards.	•	•		•	•
4.15.C	Cause a substantial permanent increase in ambient noise levels.	•	•		•	•
4.15.D	Cause a substantial temporary or periodic increase in ambient noise levels	•			•	•
4.16 – Parks and Recreation						
4.16.A	Adversely affect existing recreational resources.					•
4.17 – Public Facilities						
4.17.A	Cause adverse environmental effects due to the need for fire protection services.					•
4.17.B	Cause adverse environmental effects due to the need for law enforcement services.					•
4.17.C (1)	Adversely affect or exceed the permitted capacity of a landfill.					•
4.17.D	Cause adverse environmental effects due to the need for schools.					•
4.17.E	Cause adverse environmental effects due to the need for library services.					•
4.17.F	Cause adverse environmental effects due to the need for medical facilities.					•
4.18 – Transportation and Traffic						
4.18.A	Conflict with circulation system effectiveness regulations for any transportation.	•	•	•		•
4.18.B	Conflict with congestion management program, including LOS standards.					•
4.19 – Water Resources						
4.19.A	Result in insufficient water supply.	•	•	•		•
4.19.B	Substantially deplete groundwater supplies or substantially interfere with groundwater recharge.	•	•	•		•
4.19.H	Substantially alter existing drainage patterns resulting in substantial erosion or siltation.					•
4.19.I	Cause runoff exceeding stormwater drainage system capacities or cause substantial water pollution.					•
4.19.J	Cause significant adverse effects due to the need for new or expanded stormwater drainage facilities.					•
5.4 – Significant Irreversible Changes[3]						
5.2.B	Result in the unjustified commitment of irretrievable resources.					•
5.2.C	Result in primary or secondary impacts that generally commit future generations to similar uses.					•
5.4 – Significant Growth-Inducing Effects[3]						
5.4.A	Foster direct or indirect economic growth.					•
5.4.B	Foster direct or indirect population growth.					•
5.4.C	Result in construction of additional housing.					•
5.4.D	Remove obstacles to population growth.					•
5.4.E	Facilitate other activities leading to significant environmental effects; e.g., encroach into isolated or remote areas.					•
5.4.F	Result in population increase that may strain community services or facilities.					•

Footnotes:

1. A "significant effect on the environment" pursuant to CEQA (PRC section 21083(b)) would do any of the following:
   Substantially degrade the quality of the environment. (See discussion in Section 5.1.)
   Substantially curtail the range of environment. (See discussion in Section 5.1.)
   Achieve short-term environmental goals to the disadvantage of long-term environmental goals. (See Section 5.1.)
   Cause substantial adverse effects on human beings, either directly or indirectly. (See discussion in Section 5.3.)
   Cause effects that are individually limited but cumulatively considerable. (See discussion in Section 5.5.)
2. "Unavoidable" defined per CCR Section 15126(b) as significant "environmental effects which cannot be avoided if the proposed project is implemented." (See discussion in Section 5.1.)
3. Discussed in the section indicated, rather than in Section 5.5 (Cumulative Impacts).

Table 5.0-B: Summary of Significant Irreversible Changes and Growth-Inducing Effects

Section - Effect Category / Type of Significant Impact		Irreversible [1]	Growth-Inducing[2]
5.2 – Significant Irreversible Changes			
5.2.A	Result in a large commitment of non-renewable resources that make later removal or non-use unlikely.	•[3]	
5.2.B	Result in the unjustified commitment of irretrievable resources.		
5.2.C	Result in primary or secondary impacts that generally commit future generations to similar uses.	•	
5.2.D	Result in an environmental accident that could cause irreversible damage.		
5.4 – Significant Growth Inducing Effects			
5.4.A	Foster direct or indirect economic growth.		•
5.4.B	Foster direct or indirect population growth.		•
5.4.C	Result in construction of additional housing.		•
5.4.D	Remove obstacles to population growth.		•
5.4.E	Facilitate other activities leading to significant environmental effects; e.g., encroach into isolated or remote areas.	•	•
5.4.F	Result in population increase that may strain community services or facilities.		

Footnotes:
1. Significant "irreversible environmental changes should the project be implemented" (CCR Section 15126.2(c)), as discussed in Section 5.2.
2. Growth-inducing impacts of the project (pursuant to CCR Section 15126.2(d)), as discussed in Section 5.4.
3. Significance finding based on cumulative conditions only. See indicated section for discussion.

5.1 Significant Environmental Effects That Cannot Be Avoided

A. Introduction

State CEQA Guidelines, CCR Section 15126.2(b), specifies that an EIR must "describe any significant impacts, including those which can be mitigated but not reduced to a level of insignificance." It further directs that, "where there are impacts that cannot be alleviated without imposing an alternative design, their implications and the reasons why the project is being proposed, notwithstanding their effect, should be described." Accordingly, this section describes the significant, unavoidable impacts associated with the proposed project, GPA No. 960, in particular, those arising from future development approvals or other actions accommodated by the project pursuant to build out of the updated Riverside County General Plan.

A "significant effect on the environment" is defined under CEQA (PRC Section 21068) to mean a "substantial, or potentially substantial, adverse change in the environment." Further, CEQA Section 21083 states that a project may have a significant effect on the environment if one or more of the following conditions exist:

- The proposed project has the potential to degrade the quality of the environment, curtail the range of the environment or to achieve short-term, to the disadvantage of long-term, environmental goals.
- The possible effects of the project are individually limited but cumulatively considerable. ("Cumulatively considerable" means the incremental effects of an individual project are considerable when viewed in

connection with the effects of past projects, the effects of other current projects and the effects of probable future projects.) (See Section 5.5.)

- The environmental effects of the project will cause substantial adverse effects on human beings, either directly or indirectly. (See Section 5.3.)

As shown in Table 5.0-A, the analysis in this EIR has determined that future development within Riverside County accommodated by GPA No. 960 has the potential to result in significant environmental effects that cannot be avoided or reduced to less than significant levels through mitigation. The table summarizes the types of significant impact, as well as unavoidable impacts associated with the project. The reasons for these significant impact findings are presented below or elsewhere in Section 5 .0, as indicated. See also the corresponding parts of Section 4.0 of the EIR for additional details. As indicated in the table, there would also be several significant human effects and cumulative impacts. Note, details on these (cumulative impacts, in particular) are provided in subsequent Sections 5.3, 5.4 and 5.5, respectively.

B. Significantly Affected Resources

The following environmental resources and impacts would be significantly and unavoidably affected by the proposed project, either directly, indirectly or cumulatively, as indicated.

1. Population and Housing

Analysis indicates that the land use and policy changes proposed by GPA No. 960 would result in cumulatively significant impacts to the environment as a result of incremental increases in population growth caused both directly and indirectly. Due to the inherently growth-inducing and growth-accommodating nature of a General Plan, there is no feasible mitigation to fully reduce this cumulative impact to below the level of significance. Thus, even though project effects would be individually limited, GPA No. 960's incremental contribution to cumulative housing and population impacts may be significant and unavoidable. See Section 5.5.C.2 for full analysis and details.

2. Aesthetic and Visual Resources

Analysis indicates that the land use and policy changes proposed by GPA No. 960 would result in cumulatively significant impacts to the environment as a result of incremental adverse effects to scenic vistas; scenic resources within State Scenic Highways; and, due to light and glare. Due to the widespread effect of incremental growth accommodated by a General Plan, there is no feasible mitigation to fully reduce this cumulative impact to below the level of significance. Thus, even though project effects may be individually limited, GPA No. 960's incremental contribution to these cumulative aesthetic and scenic impacts would be significant and unavoidable. See Section 5.5.C.3 for full analysis and details.

3. Agricultural Resources

Cause Direct or Indirect Conversion of Designated Farmlands: The specific land use and policy changes proposed by GPA No. 960 would adversely affect (i.e., result in the conversion of) only minimal amounts of State-designated Prime Farmland, Farmland of Statewide Importance and Farmland of Local Importance ("Farmlands") to a variety of non-agricultural uses. Due to the very small areas involved, these impacts would be less than significant. Indirectly, however, the growth accommodated and facilitated by the project would result in

additional development and infrastructure demand that would further conversion of designated Farmlands to urban uses and result in other changes in the existing environment leading to additional Farmland conversion. This indirect impact would be *a* significant and an unavoidable consequence of General Plan build out. It would also be cumulatively significant (see Section 5.5.C.4 for discussion). Section 4.5 (Agricultural and Forestry Resources) addresses this resource and includes a variety of existing County ordinances and General Plan policies that would mitigate some of these project effects.

Compliance with these regulations and General Plan policies would help reduce this indirect impact. However, consistent with the findings made previously for the General Plan in EIR No. 441, there is no feasible CEQA-specific mitigation that would fully reduce this impact to less than significant levels. This is because growth within Riverside County (occurring as the natural consequence of human population growth) requires the use of land, including designated Farmlands in some areas, to support future development. Where such Farmlands occur amidst or adjacent to urbanizing areas, the natural extension of development is inevitable and, in fact, desirable (as opposed to leapfrog or fragmentary development further away which would lead to urban sprawl). Where encroachment causes open agricultural lands, such as fallow fields, pastures or rangelands, for example, to become urbanized or otherwise limited, significant curtailment of the natural environment would result. For these reasons, this indirect impact would remain significant and unavoidable.

Agricultural resources would be subject to significant and unavoidable conversions of designated farmlands to non-agricultural uses. This impact cannot be avoided or reduced to less-than-significant due to the sprawling and wide-spread nature of existing agricultural uses and the myriad of growth pressures fueling growth and ongoing development. As a result, this impact would lead to the curtailment of the range of available designated farmlands within Riverside County. Also, as discussed in Section 5.5.C.4, many of these effects would be individually limited by cumulatively considerable on a countywide basis. Thus, in total, because of the need to designate appropriate areas of growth within the General Plan, even on various Farmlands, GPA No. 960 is proposed despite this significant, unavoidable impact.

Encroach on or Conflict with Existing Agricultural Uses: Future development accommodated by GPA No. 960 has the potential to result in conflicts with existing zoning, agricultural uses and lands subject to a Williamson Act contract or within a Riverside County Agricultural Preserve. It may also result in the introduction of new urban uses near or adjacent to agriculturally zoned property. Urban encroachment into areas in agricultural production, particularly if within 300 feet, increases the likelihood of conflicts between these two fundamental types of uses. When residential and other urban-density land uses encroach into areas in agricultural production, traditional agricultural nuisances become much more problematic to the arriving residents. For farmers, urban encroachment adversely affects the efficiency of remaining farming operations due to increased air pollution, livestock predation by pets, crop diseases resulting from inadequate care of off-farm ornamental plants, restrictions on pesticide use and burning, and requirements to set aside on-farm buffer zones. At the same time, production costs increase due to rising land values, water scarcity, theft and vandalism of farm equipment, crop pilferage, road congestion, change in property tax structure and personal injury liability resulting from trespassing on farms.

Because this impact represents the consequence of urbanization, it would be significant and unavoidable. As outlined in Section 5.5, it would also be cumulatively significant where small, individual future changes would be individually limited, but cumulatively considerable on a countywide basis. Section 4.5 addresses this resource and includes a variety of Riverside County ordinances and existing and proposed General Plan policies that would help lessen or reduce this project effect. However, consistent with the findings made previously for the General Plan in EIR No. 441, there is no feasible CEQA-specific mitigation that would reduce this impact to less than significant levels. This is because growth within Riverside County (occurring as the natural consequence of human population growth) requires the use of land, including designated Farmlands in some areas, to support

future development. Where such Farmlands occur amidst or adjacent to such urbanizing areas, the natural extension of development is inevitable and, in fact, desirable (as opposed to leapfrog or fragmentary development further away which would lead to urban sprawl). Although buffers are effective, they cannot prevent or guarantee the complete avoidance of these conflicts. Thus, for these reasons, this impact would remain significant and unavoidable.

For all of these reasons, existing agricultural activities would be subject to significant and unavoidable conflicts resulting from the encroachment of urban uses into rural and agricultural areas as Riverside County continues to grow over the next 50 years. This impact also cannot be avoided or reduced to less-than-significant because of the finite land supply, the sprawling and wide-spread nature of existing agricultural uses and myriad growth pressures fueling growth and ongoing development. As a result, this impact would lead to the potential degradation of the quality of the environment within Riverside County. Also, as discussed in Section 5.5.C.4, many of these effects would also be individually limited but cumulatively considerable on a countywide basis.

4. Air Quality

Air pollutant emissions are generally associated with two types of activities: construction and operation. Because of their limited spans, construction impacts are considered a "short-term" effect. Operational emissions are considered "long-term," since they would occur for the duration of a development or land use's lifespan (often 30 years or more). As part of this EIR's analysis, both short-term and long-term air quality emissions were examined with respect to GPA No. 960. In both cases, it was found that significant unavoidable impacts would occur as a result of the cumulative effects of various air quality emissions. In some cases, a future project could itself exceed applicable AQMD emission standards for construction or operation. Even in cases where emissions could be individually reduced to acceptable levels, the cumulative effect of multiple activities (construction and operation) occurring simultaneously would result in cumulatively significant emissions at the countywide or regional level. The specific types and their unique effects and mitigation needs are described below. Cumulative impacts, including those associated with air quality, are discussed in detail in Section 5.5.C.5.

Because air quality impacts result from the general growth pressures driving development within Riverside County, they are generally considered unavoidable; as long as people seek to live and work in Riverside County, these impacts will persist. It is possible that continued technological advancements, such as electric vehicles, solar power and alternative energy, will reduce air quality emissions in the future. However, the use of such technology will likely occur incrementally over many decades and will require drastic price reductions before full market penetration can be achieved throughout Riverside County. This means that for all intents and purposes, the air quality impacts described below must be considered unavoidable for the time being.

Conflict with Air Quality Plans: Analysis indicates that the land use and policy changes proposed by GPA No. 960 would result in incremental changes due to growth that causes cumulatively significant impacts due to conflicts with air quality plans. Due to the wide-spread effect of incremental growth accommodated by a General Plan, there is no feasible mitigation to fully reduce this cumulative impact to below the level of significance. Thus, even though project effects may be individually limited, GPA No. 960's incremental contribution to these cumulative air quality impacts would be significant and unavoidable. See Section 5.5.C.5 for full analysis and details.

Cause Significant Construction (Short-Term) Air Emissions: As explained in Section 4.6 (Air Quality), future development accommodated by GPA No. 960 would necessitate construction activities that could cause temporary (short-term), generally localized increases in the emission of air pollutants. In some cases, individual project construction emissions could exceed established regulatory standards. The construction emissions generated are quantified based on the amount of daily disturbance (e.g., acres graded per day, structures painted

per day, etc.). Accordingly, significant air quality emissions associated with an individual project or site can be avoided by limiting the amount of construction activities occurring on a single day.

However, since build out of Riverside County pursuant to the General Plan and GPA No. 960 would be implemented through many (hundreds or even thousands) of individual projects occurring throughout Riverside County over next roughly 50 years, the total (cumulative) level of daily disturbance for GPA No. 960 cannot be quantified in aggregate. The amount of construction activities necessary to exceed a daily standard is known, however. And, since the County of Riverside cannot control the number of construction activities collectively occurring on any given day, cumulatively considerable emissions could result from the compliant emissions of many individual sites occurring on a single day. See Section 5.5.C.5 for full analysis and details.

As outlined in Section 4.6, the County General Plan and this EIR incorporate a variety of regulatory actions and mitigation measures that would avoid, reduce or minimize individual project emissions; however, there is no mitigation feasible for further reducing the cumulative impact at the county level. The cumulative effect of air pollutants associated with construction activities within Riverside County would result in significant and unavoidable impacts that collectively degrade the quality of the environment.

Cause Significant Operational (Long-Term) Air Emissions: Operational long-term air emissions are associated with both mobile sources (i.e., vehicle), stationary sources (i.e., boilers, heaters, stoves and ovens, fireplaces and other fixed-source emitters) and also area sources (i.e., gasoline-powered landscape equipment, such as mowers and leaf-blowers, paints and other household chemicals, etc.) located on or associated with developed land uses. As explained in Section 4.6, future development would also result in operational air quality emissions from combustion-powered equipment associated with these new uses. In some cases, these emissions may be significant – exceeding the daily emissions limits established by the overseeing regulatory agency (e.g., the SCAQMD).

In many of these cases, air quality emissions associated with an individual project or site can be avoided, reduce or minimized through regulatory compliance and mitigation measures. However, on a cumulative basis, the individual emissions would still be cumulatively considerable. (See Section 5.5.) This is particularly true of the increased emissions expected to arise from additional vehicle trips within Riverside County.

The Riverside County General Plan and this EIR incorporate a variety of regulatory actions and mitigation measures that would avoid, reduce or minimize operational emissions. However, there is no mitigation feasible for further reducing the cumulative impact at the county level. Thus, the cumulative effect of air pollutants associated with operational emissions within Riverside County would result in significant and unavoidable impacts that collectively degrade the quality of the environment. For these reasons, development accommodated by the project would result in significant, unavoidable long-term operations air quality impacts, even after all feasible mitigation measures are implemented. Even with the implementation of regulations, ordinances and existing and proposed General Plan policies, in addition to new mitigation measures, cumulative criteria pollutant emissions would not be reduced below regulatory thresholds. Thus, this impact would remain significant and unavoidable with respect to violations of air quality standards for operational activities. Further, this significant impact would result in direct and/or cumulative degradation of the quality of the environment (specifically, air), as a result of this project.

Cause Cumulatively Significant Project Air Quality Impacts: Future development accommodated by GPA No. 960 would also result in the emission of criteria pollutants for which Riverside County is in non-attainment during both its construction and operation (as discussed above). Since the exact location, timing and duration of future development projects cannot be ascertained at this time, cumulatively considerable increases to criteria pollutant levels (resulting from multiple projects engaging in construction and/or operational emissions at the

same time) cannot be quantified. Even with compliance with existing regulations and policies and the implementation of existing and new mitigation measures, as outlined in Section 4.6 for Impact 4.6.C, future development accommodated by the project would result in significant cumulative impacts that degrade the quality of the air in Riverside County. Since these impacts arise from the cumulative effects of many sites developing over time, which is driven by growth pressures in the county, they are also considered unavoidable.

Expose Sensitive Receptors to Air Pollutants: Sensitive receptors are those areas where sensitive populations (which include children, the elderly, the acutely ill and the chronically ill, especially those with cardio-respiratory diseases) may be present for extended periods of time, resulting in sustained exposure to pollutants emitted in the area. Future development accommodated by GPA No. 960 would expose sensitive receptors to pollutant emissions due to construction (where such construction is adjacent to a sensitive receptor) and operational activities (particularly where increases in emissions, such as from motor vehicles, would increase emissions near existing uses).

The degree of impact would depend on the type of operation, distance from sensitive receptors and the level of activity at each site. The exact location, timing and level of future development activities arising from GPA No. 960 is unforeseeable, however, so specific impacts to sensitive receptors cannot be quantified. Further, though individual projects may successfully mitigate significant effects, on a cumulative basis, a collection of several such projects could nevertheless exceed limits on exposure to sensitive receptors, resulting in effects to humans (see Section 5.3) and degradation of the environment. Thus, even after complying with regulations, existing policies and mitigation measures, as well as specific new mitigation measures, cumulatively these impacts cannot be guaranteed to be reduced to below applicable agency thresholds. In addition, although mitigation is available and is incorporated into both the General Plan and this EIR, full mitigation is infeasible because it would require prohibiting many types of development, including most types of infill, for example. For these reasons this impact would be significant and unavoidable. Thus, GPA No. 960 is proposed despite its significant, unavoidable effects on air quality because the project is necessary to ensure future growth in Riverside County occurs in a coordinated and appropriate manner to accommodate Riverside County's population and work force.

5. Greenhouse Gases

Analysis indicates that the land use and policy changes proposed by GPA No. 960 would incrementally contribute to cumulatively significant environmental effects due to greenhouse gases (GHGs). In particular, GHG emissions occurring within Riverside County between 2020 and 2060 would be cumulatively significant and unavoidable because they would contribute to GHG levels in excess of the 2050 mitigation targets established for California under Executive Order S-3-05, i.e., reducing GHG emissions to "80% below 1990 levels by 2050." The County is committed toward the reduction of GHG emissions. However, the means to achieve the 2050 reduction target is technologically infeasible at this time. Mitigation Measure 4.7.A-.N3 requires the County to provide by January 1, 2020, a post-2020 CAP that includes 2035 and 2050 reduction targets and specific reduction measures to achieve those targets. This allows technology, the State and the County the time needed to develop reduction measures able to achieve the 2050 reduction target. At present, however, there is no feasible mitigation to fully reduce this cumulative impact to below the level of significance in terms of 2050 targets. Thus, even though project effects may be individually limited, GPA No. 960's incremental contribution to these cumulative greenhouse gas impacts would be significant and unavoidable. See Section 5.5.C.6 for full analysis and details.

6. Cultural and Paleontological Resources

Analysis indicates that the land use and policy changes proposed by GPA No. 960 would result in cumulatively significant impacts to the environment as a result of incremental adverse effects due to the destruction of both known archeological resources and unique paleontological resources and sites. Due to the wide-spread effect of incremental growth accommodated by a General Plan, there is no feasible mitigation to fully reduce this

cumulative impact to below the level of significance. Thus, even though project effects may be individually limited, GPA No. 960's incremental contribution to these cumulative cultural and paleontological impacts would be significant and unavoidable. See Section 5.5.C.8 for full analysis and details.

7. Energy Resources

Implementation of the General Plan as amended pursuant to the proposed project, GPA No. 960, would result in cumulatively significant impacts to the environment as a result of incremental increases in the demand for both electricity and natural gas. Due to the wide-spread effect of incremental growth accommodated by a General Plan, there is no feasible mitigation to fully reduce this cumulative impact to below the level of significance. Thus, even though project effects may be individually limited, GPA No. 960's incremental contribution to these cumulative energy impacts would be significant and unavoidable. See Section 5.5.C.9 for full analysis and details.

8. Geology and Soils

Analysis indicates that the land use and policy changes proposed by GPA No. 960 would result in cumulatively significant impacts to the environment as a result of incremental exposure of people and structures to A) strong seismic groundshaking; and, B) landslides. Due to the wide-spread effect of incremental growth accommodated by a General Plan, there is no feasible mitigation to fully reduce this cumulative impact to below the level of significance. Thus, even though project effects may be individually limited, GPA No. 960's incremental contribution to these cumulative geological impacts would be significant and unavoidable. See Section 5.5.C.11 for full analysis and details. These impacts are also addressed because of their potential to result in significant and unavoidable effects to humans. See Section 5.3 (Substantial Human Effects) for more details.

9. Hazardous Materials and Safety

Implementation of the General Plan as amended pursuant to the proposed project, GPA No. 960, would result in cumulatively significant impacts to the environment as a result of incremental exposure of people and structures to increased risks of wildland fires because of the additional development, particularly large-lot open space-rural residential (OS-RUR) in high- and very high-fire hazard severity zones, that would be accommodated by this project. Due to the wide-spread effect of incremental growth accommodated by a General Plan, there is no feasible mitigation to fully reduce this cumulative impact to below the level of significance. Thus, even though project effects may be individually limited, GPA No. 960's incremental contribution to this cumulative safety hazard would be significant and unavoidable. See Section 5.5.C.12 for full analysis and details. This impact is also addressed due to its potential to result in significant and unavoidable effects to humans. See Section 5.3 for more details.

10. Noise

As explained in Section 4.15 (Noise), noise increases are generally associated with two types of activities: construction and operation. Because of their limited spans, construction impacts are considered a "short-term" effect. Operational noise increases are considered long-term, since they would occur for the duration of a development or land use's lifespan (e.g., 30-plus years). As part of this EIR's analysis, both short-term and long-term potential for noise increases were examined with respect to GPA No. 960. In both cases, it was found that significant unavoidable impacts would occur as a result of the cumulative effects of various noise level increases and, in particular, that these cumulative totals would result in noise levels exceeding standards. This would both degrade the environment (making it unpleasantly noisy, for example) and/or curtail the range of the environment

(by making an area too noisy for wildlife use, as another example.) The specific types and their unique effects and mitigation needs are described below. Cumulative impacts, including those associated with noise, are discussed further in Section 5.5.C.14.

Because noise impacts result from the general growth pressures driving development within Riverside County, they are generally considered unavoidable; as long as people seek to live and work in Riverside County, these impacts will persist. It is for this reason that GPA No. 960 is proposed despite this significant, unavoidable impact. In some parts of Riverside County, noise levels already exceed established standards. In some locations, significant effects would persist, even without the additional development expected as Riverside County builds out according to the updated General Plan. Further, this also means that in some areas, even small, individually limited noise increases would contribute to incrementally considerable noise levels. This is particularly true of the ambient noise levels increases associated with increasing vehicular traffic on county roads. Overall, this means that for all intents and purposes, the noise impacts described below are unavoidable. Noise level increases, both temporary and permanent, would also contribute to the cumulatively significant noise impacts (see Section 5.5.C.14).

Generate Noise or Cause Noise Exposure in Excess of Standards: Future development accommodated by GPA No. 960 would incrementally increase rural, suburban and urban uses in localized areas throughout unincorporated Riverside County. In some locations, this means the introduction of new noise-sensitive land uses into areas of existing excess noise or areas in which county growth would result in or eventually lead to excess noise levels. In addition, future development accommodated by GPA No. 960 would contribute incrementally to increased traffic volumes on county roads, resulting in noise increases affecting sensitive land uses along existing and future roads. As a result, new development, particularly residential uses along and adjacent to major transit corridors, could be exposed to noise levels that exceed Riverside County's noise standards. Existing sensitive uses would also be subject to these higher noise levels. In some locations, noise increases associated with roadways or new development would serve to curtail the potential habitat functions and values of adjacent open space or other vacant lands. Where noise generators would expose existing receptors (residences and other sensitive uses) to excessive noise, impacts would be significant and unavoidable, as mitigation of these incremental and wide-spread noise impacts is infeasible. Thus, this impact would result in both the degradation of the environment and significant human effects (see Section 5.3).

In most cases, new development can be designed to include the necessary setbacks, construction materials, sound walls, berms or other features necessary to ensure internal and external noise levels meet applicable standards (see measures outlined in Section 4.15.6). Where full mitigation may not be possible, however, is for noise exposure to existing uses, particularly to excessive roadway noise. Roadway noise is pervasive and increases incrementally as a result of build out of many small (and large) contributing developments throughout the county. As a result, numerous existing homes and other sensitive receptors could potentially be subjected to significant noise levels as a result of future development accommodated by the project. In some cases, mitigation of the excessive sound impacts on existing uses would be infeasible due to the sheer number of sites affected (e.g., hundreds or even thousands of homes) or the cost for retrofitting them individually for appropriate sound attenuation. In other cases, it simply may not be feasible to retrofit or redesign an existing receptor to provide greater noise attenuation and it is not always feasible to construct barriers between existing development and roadways.

In addition, the increases would be occurring on an incremental basis as a result of numerous individually insignificant, but cumulatively substantial, traffic level increases due to future projects. And, lastly, in many cases, even if adequate sound reductions are achievable for the near-term (e.g., existing conditions and the next 5-10 years), continued growth within Riverside County as it builds out over the next 50 years could eventually result in substantial ambient noise level increases later despite current measures. It is for this reason that GPA No. 960 is proposed despite this significant, unavoidable impact. While mitigation is available for protecting new noise-

sensitive land uses from potentially significant noise impacts, the same is not true for existing uses. Thus, this impact overall is a significant and unavoidable effect associated with the build out of Riverside County pursuant to the changes proposed by GPA No. 960.

Cause a Substantial Permanent Increase in Ambient Noise Levels: Future development associated with implementation of GPA No. 960 would contribute to an increase in traffic, resulting in a corresponding increase in traffic noise. As Riverside County builds out, traffic volumes would increase, triggering a corresponding incremental increase in vehicular noise. Vehicles are the single largest source of noise generation throughout Riverside County. In some areas, this would cause ambient noise to increase from acceptable to unacceptable levels (exceed 65 dBA, for example). Where existing ambient noise levels already exceed acceptable thresholds, the additional incremental traffic-related increase could result in greater noise impacts, including more people being annoyed or disturbed. Also, because of the exponential nature of sound levels, the louder the ambient noise level, the less increase in sound necessary to trigger a significant impact. Also, as per above, noise increases associated with roadways or new development would serve to curtail the potential habitat functions and values of adjacent open space or other vacant lands.

For new development, full mitigation would typically be feasible using standard project design or measures required as conditions of approval (for example, setbacks, sound walls, berms, etc.). For existing noise-sensitive land uses, however, due to the widespread and pervasive nature of the noise impacts, it is generally not be feasible to mitigate the impact fully for all affected receptors. Thus, this impact would be significant and unavoidable, even with the implementation of all feasible mitigation. It would result in both the degradation of the environment and significant human effects (see Section 5.3). Nevertheless, because permanent ambient noise levels would increase as a result of county growth, with or without the project, GPA No. 960 is proposed despite this significant, unavoidable impact.

Cause a Substantial Temporary or Periodic Increase in Ambient Noise Levels: Future development accommodated by GPA No. 960 would necessitate construction activities which could temporarily exceed applicable Riverside County standards at nearby noise-sensitive receptors. In many cases, the peak sound levels would be extremely brief and overall ambient noise levels would remain within acceptable limits. On occasion, however, construction requirements and/or the proximity of the sensitive land use (e.g., within 150 feet or less) would make significant noise impacts unavoidable, even though temporary. These temporary impacts would degrade the environment and also cause temporary human impacts (see Section 5.3). Because of the close distances involved for such significant impacts, mitigation of sound levels to less than significant are technologically impossible. Thus, in such cases, no project-specific mitigation is feasible. Future development accommodated by GPA No. 960 may result in significant short-term temporary noise impacts that would be significant and unavoidable. Notwithstanding this significant impact, growth within Riverside County is necessary to accommodate the expected population increase that will occur over the next 50 years plus. It is for this reason that GPA No. 960 is proposed despite this significant, unavoidable impact.

11. Parks and Recreation

Implementation of the General Plan as amended pursuant to the proposed project, GPA No. 960, would result in cumulatively significant impacts to the environment as a result of incremental adverse effects to existing recreational resources, including parks, trails and other facilities. Due to the wide-spread effect of incremental growth accommodated by a General Plan, there is no feasible mitigation to fully reduce this cumulative impact to below the level of significance. Thus, even though project effects may be individually limited, GPA No. 960's incremental contribution to this cumulative recreation impact would be significant and unavoidable. See Section 5.5.C.15 for full analysis and details.

12. Public Facilities and Services

Analysis indicates that the land use and policy changes proposed by GPA No. 960 would result in cumulatively significant impacts to the environment as a result of incremental adverse effects to public facilities and services, including: fire protection, law enforcement, landfill capacity, schools, library services and, medical facilities and services. Due to the widespread effect of incremental growth accommodated by a General Plan, there is no feasible mitigation to fully reduce this cumulative impact to below the level of significance. Thus, even though project effects may be individually limited, GPA No. 960's incremental contribution to these cumulative public facility and service impacts would be significant and unavoidable. See Section 5.5.C.16 for full analysis and details.

13. Transportation and Circulation

Implementation of the existing and proposed General Plan policies and mitigation measures would reduce many of the potential traffic impacts on Riverside County's arterial transportation and circulation system resulting from the future development of sites changed under GPA No. 960. However, in some locations, such as certain arterials and other major roads, the cumulative increase in traffic resulting from future development and growth within Riverside County in general would result in significant localized impacts. And, as alternative modes of transportation cannot be assured to reduce these impacts, these traffic increases are also considered unavoidable. See Section 5.5.C.17 for full analysis and details on cumulative impacts.

In addition, all state freeways are under the authority of Caltrans. Thus, where traffic increases would affect freeways, there is no mechanism for development project proponents to pay fees or make fair share contributions toward improving mainline freeway lanes. Also, even if there were such a mechanism, there is no way to ensure that such payments would be directed to a specific freeway improvement project. Consequently, there are no feasible mitigation measures for impacts to freeways; impacts would be significant and unavoidable.

Conflict with Circulation System Effectiveness Regulations for Any Form of Transportation: These impacts would facilitate the achievement of short-term goals to the disadvantage of long-term environmental goals. The provision of county roads would result in improved traffic flow in some areas, while at the same time contributing to increases in air pollutants, noise and traffic volumes. This impact would also indirectly degrade the environment and curtail the environmental functions and values of open lands through the introduction of roads into previously undeveloped or remote areas. This would lead to increased noise, air pollution, human disturbance and other related environmental effects. Altogether, this impact is significant and unavoidable.

14. Water Resources

Future development accommodated by GPA No. 960 would result in additional residences, businesses, landscaping, roadways and other uses within unincorporated Riverside County. A number of factors associated with water supplies make the resource of critical importance and a potentially limiting factor to growth throughout Southern California. These include: uncertainty associated with existing imported water supplies, seasonal variations in imported water availability (including the potential for greater variations as a result of global climate change or prolonged droughts), infrastructure needs (or lack thereof), groundwater basin water availability, recharge and potential overdraft issues, as well as lack of groundwater management plans for some basins and competing demands for finite supplies. Together, these issues make for a high level of uncertainty, particularly for projections of water availability beyond the 20-year planning horizons utilized by water agencies' urban water management plans.

Accordingly, several significant impacts to water resources will result from implementation of the General Plan pursuant to the changes proposed by GPA No. 960. In addition to the other issues discussed below, analysis indicates that the land use and policy changes proposed by GPA No. 960 would result in cumulatively significant impacts to the environment as a result of incremental adverse effects resulting in insufficient water supply; substantial depletion of groundwater supplies or substantial interference with groundwater recharge; substantial alteration of existing drainage patterns resulting in substantial erosion and/or siltation; runoff exceeding storm-water drainage system capacities or causing substantial water pollution; and, adverse effects due to the need for new or expanded stormwater drainage facilities. Due to the wide-spread effect of incremental growth accommodated by the General Plan, there is no feasible mitigation to fully reduce this cumulative impact to below the level of significance. Thus, even though project effects may be individually limited, GPA No. 960's incremental contribution to these cumulative water resource impacts would be significant and unavoidable. See Section 5.5.C.18 for full analysis and details.

Result in Insufficient Water Supply: Future development accommodated by the land use and policy changes proposed by GPA No. 960 has the potential to result in demand for water supplies where such are insufficient or unavailable to serve the new development from existing entitlements and resources. This would necessitate the provision of new or expanded entitlements in order to adequately serve the new development. It could also mean that development is proposed in locations where water supply adequacy cannot be ascertained. Due to the unavailability of potable water in some areas, as well as the uncertainty of supply adequacy in light of future growth, environmental and regulatory constraints, adequate water supplies for all forecast future development cannot be assured. As a result, within certain areas of Riverside County where sufficient water supply is not available or cannot be assured into the future, impacts to water supply would be significant and unavoidable. Insufficient water supplies would also result in degradation of the environment (for example, if more water needed for wildlife use was diverted for drinking water supplies), curtailment of the environment (e.g., less water in natural systems needed for wildlife and riparian uses), as well as achievement of short-term environmental goals at the expense of long-term ones (for example, providing sufficient high-quality drinking water at the expense of the biota).

As described in Section 4.19.4, some water districts that would be affected by future development accommodated by GPA No. 960 have forecast future water demands in excess of the supply available. Where demand for water exceeds supply, a significant impact would occur. In some remote locations (particularly in the far eastern desert, beyond the Coachella Valley and the region south of the San Jacinto Mountains between Anza and Coachella Valley), lack of groundwater and/or lack of delivery infrastructure also are limiting factors. For all of these reasons, the impact of water supply insufficiency is deemed significant and unavoidable at this time.

Options available to address potential projected water shortfalls include both infrastructure projects (such as storage facilities and water reclamation plants) and water management strategies (such as conservation practices) that relate to how water is used by and among water users. However, the urban water management plans of the water districts only project water supply and demand out 25 years (to 2035 currently). Thus, any assumptions of future water supplies beyond 2035 are speculative. The General Plan and GPA No. 960 include policies (discussed in Sections 4.19.5.D and E) that establish and reiterate appropriate water management strategies at the county level, including conservation, collection of information, decreasing demand, outreach and education programs, assurances of adequate groundwater recharge areas and water supply monitoring.

Securing additional imported water is another way to increase the water supply. This water could come from existing imported sources (i.e., the Colorado River or other State Water Project sources), or could come from yet-to-be negotiated sources. It is possible that these measures would, in the future, be sufficient to avoid significant water supply effects. However, in the absence of a definitive identification of future water supply, potential impacts associated with water supply and demand must be considered significant and unavoidable. Notwith-

standing this significant impact, most of the urban areas of Riverside County are served by urban water purveyors with urban water management plans indicating that they have sufficient water supplies to meet their projected water demands for the next 25 years. This near-future certainty is sufficient to accommodate development in the near-term. As time passes, water projections will become more accurate and State of California water plans more robust, providing additional certainty over time. It is for these reasons that GPA No. 960 is proposed despite this significant, unavoidable impact.

Substantially Deplete Groundwater Supplies or Cause Overdraft: Future development accommodated by the land use and policy changes proposed by GPA No. 960 would increase Riverside County's population, triggering an increased reliance on groundwater sources. This is particularly likely in areas of Riverside County without municipal water service or other access to imported water supplies, where new development would rely solely on groundwater for supply. Increased and new uses may also conflict with a groundwater management plan or monitoring program, or lead to groundwater extraction that either individually or cumulatively exceeds the safe yields of groundwater basins and/or causes a net deficit in the aquifer volume or reduction in the local groundwater table level. In addition, future development accommodated by the project could also occur in vacant areas currently used for or contributing to groundwater recharge. Development of such areas would reduce the area available for aquifer recharge and could substantially interfere with the process of groundwater recharge. Any such condition could be potentially significant and would result in significant degradation of the environment (e.g., where increased reliance on groundwater would mean an increased reliance on water of lower quality) and/or result in significant curtailment of the environment (e.g., where draw down on a groundwater basin could lessen the amount of water available for riparian systems and other biota relying on groundwater). Lastly, this could also result in that achievement of short-term environmental goals to the detriment of long-term ones. This could occur where the use of groundwater solves a short-term environmental problem of insufficient water supply, but causes a long-term problem due to overdraft of the basin, reducing available supplies for both human users and that biota relying on the basin. A number of regulatory policies and programs address groundwater. However, where groundwater recharge is insufficient, such increased demand on aquifers would result in significant and unavoidable impacts.

The combination of increased demand for water associated with the growth envisioned by the project, uncertainty and cost of imported water supply, uncertainty of long-term supply scenarios in non-adjudicated basins, exploitation of new groundwater sources and the continuing pattern of basin overdraft, would all result in or contribute incrementally to substantially decreasing groundwater supplies. In addition, an assessment of future water supply adequacy beyond the Year 2035 (including groundwater) is speculative. And, since at present roughly one-third of Riverside County's water demands are met by groundwater, this uncertainty means that significant impacts associated with project build out over the next 50-plus years cannot be ruled out.

While the regulations, ordinances, General Plan policies and existing mitigation measures from EIR No. 441 outlined in Section 4.19 would reduce or minimize potential impacts to groundwater usage and its recharge associated with future development accommodated by GPA No. 960, they do not address specific groundwater basin usage or site-specific groundwater recharge impacts that would result indirectly from implementation of the proposed project. In addition, agency data demonstrating future groundwater supply and demand only forecast to 2035, thus making supply assumptions for this project uncertain at best. Thus, even with the above measures, impacts to groundwater and groundwater recharge would remain significant and unavoidable.

Notwithstanding this significant impact, most of the urban areas of Riverside County are served by urban water purveyors with urban water management plans that address both imported and groundwater sources. Further, most of these plans indicate that the districts have sufficient water supplies to meet their projected water demands for the next 25 years, even allowing for appropriate groundwater management measures to prevent overdraft. This near-future certainty is sufficient to accommodate future development in the near-term. As time passes,

groundwater basin conditions will become better studies and better managed and groundwater yield and recharge projections will become more accurate, providing additional certainty over time. It is for these reasons that GPA No. 960 is proposed despite this significant, unavoidable impact.

C. Other CEQA Impacts

In addition to the significant resource-based environmental impacts discussed above, the project would also have significant, unavoidable impacts resulting from various growth-inducing, cumulative and other effects, as follows.

1. Significant Growth Inducement Effects

Based on analysis presented in Section 5.4, it was determined that a number of the proposed changes associated with GPA No. 960 would limit or impede growth (for example, by placing further restrictions on floodplains or wildfire hazard areas) or would induce insignificant amounts of growth (less than 0.1% of the overall growth by Area Plan, for example). An example would be the provision of small, scattered incidental rural-commercial retail uses in under-served regions that is expected to result from the proposed incidental rural-commercial policy proposal. However, for land use, three specific overlay plans for future development proposed under GPA No. 960 would have the potential to induce significant growth within Riverside County. The three project components that would foster economic, population and housing growth within a portion of Riverside County are the proposed Meadowbrook Rural Village Land Use Overlay, the Good Hope Rural Village Land Use Overlay and the Northeast Business Park Overlay. The significant levels of growth associated with these three land use plans would result in the unavoidable growth impacts. These impacts are unavoidable because the population to be accommodated in these new areas would be creating similar impacts elsewhere if not at these new locations. Further, the accommodation of additional development in these locations could also offset the demand for development at more distant locales in which development impacts would be even greater.

As detailed in Section 5.2, and Table 5.2-A (Open Space Areas Proposed for Future Developed Uses) in particular, "Criteria 4" land use designation (LUD) changes (from Open Space-conservation and conservation habitat uses to developable uses) would also result in significant growth-inducing impacts. These redesignations of previously undevelopable lands are growth-inducing because they would introduce development into isolated or remote areas. However, this impact is unavoidable because without these designation changes, private lands would be incorrectly designated as conservation lands and deprived of their usability as private land.

In addition, proposed changes to the countywide circulation network could also induce significant growth due to the essential nature of roads in providing access to remote or isolated regions, and in removing impediments to growth by establishing an essential public facility. Again, these impacts are unavoidable due to the need for access to private lands that would trigger some of the most remote roads. The need for improved traffic circulation, reduced traffic levels and improved emergency vehicle access also make these network improvements unavoidable despite their significant growth-inducing effects.

These finding of significant growth-inducing effects associated with GPA No. 960 are not unexpected given the programmatic nature of the project, its countywide scope and the nearly 50-year build out period involved. The nature and purpose of the General Plan is inherently growth inducing, in that is represents a plan for ensuring the orderly development of land within unincorporated Riverside County over time. As such, the myriad policies, plans, procedures and standards outlined throughout the Riverside County General Plan, as updated pursuant to GPA No. 960, as well as this EIR and also the existing EIR No. 441, certified for the 2003 RCIP General Plan, collectively serve to mitigate and reduce, where possible, the severity of the environmental effects associated with growth and build out of Riverside County. With continued diligence in implementing the General Plan, long-

term growth within the County of Riverside can continue while environmental effects are kept to the minimum feasible and the unique biological and other important natural resources of Riverside County are protected for the health and enjoyment of existing residents and visitors, as well as for future generations to come. Thus, for these reasons, GPA No. 960 is proposed despite these significant, unavoidable growth-inducing impacts.

2. Significant Effects on Humans

As outlined in Section 5.3, a number of environmental effects associated with the project, GPA No. 960, have the potential to result in "environmental effects which [would] cause substantial adverse effects on human beings, either directly or indirectly." (State CEQA Guidelines, Appendix G, Item XVIII.c.) The specifics for each of these impacts are outlined in their respective portions of Section 4.0, as well as in Section 5.3. In a few cases, the project would have substantial direct adverse effects on humans. These unavoidable direct effects include the following:

- Exposure of sensitive receptors (e.g., various populations of people with sensitive respiratory systems) to cumulatively significant levels of air pollutants. See Impact 4.6.D in Section 4.6.6, as well as Section 5.3.

- Exposure of people to noise levels in excess of standards. See Impact 4.15.A in Section 4.15.6, as well as Section 5.3. This cumulatively substantial and unavoidable noise impact would affect people where such noise exposure is above the acceptable noise levels established in various County of Riverside and State of California noise standards.

Most of the substantial adverse human impacts would occur indirectly as a result of various cumulative or growth-associated effects. They are unavoidable because they would occur as a result of many individually insignificant, but cumulatively considerable, impacts. These include the following:

- Safety risks to humans due to their potential exposure to strong seismic groundshaking (Impact 4.12.B) would result from growth within Riverside County. This indirect impact is an unavoidable risk associated with much of Southern California due to proximity to the San Andreas Fault and other major faults capable of producing strong groundshaking. See Section 4.12 (Geology and Soils) for full details.

- Safety risks to humans would result from their potential exposure to landslide hazards due to seismic activity or other non-engineering based geological failures. See Impact 4.12.D (Section 4.12.6). This indirect impact is an unavoidable cumulative effect of growth resulting in development in areas with landslide hazards that cannot be remedied by engineering methods.

- Safety risks to humans due to their potential exposure to wildfires would result from county growth (development) in areas with high wildfire hazard potential, particularly in rural areas and adjacent to natural areas. See Impact 4.13.H outlined in Section 4.13 (Hazardous Materials and Safety). This indirect impact is an unavoidable cumulative effect of growth leading to an increased number of people in areas of wildfire hazard and increased potential for human-caused wildfires due to increased human encroachment into wildlands.

- Adverse effects on humans through a substantial permanent increase in ambient noise levels. See Impact 4.15.C (in Section 4.15.6). This cumulatively substantial and unavoidable permanent noise increase would affect people where such long-term exposure is above the acceptable noise levels established in various County of Riverside and State of California noise standards.

- Adverse effects on humans through the temporary exposure to substantial construction-related ambient noise levels. See Impact 4.15.D (in Section 4.15.6). This cumulatively substantial and unavoidable temporary noise increase would affect people where such exposure is above the acceptable noise levels established in various County of Riverside and State of California noise standards. Due to the temporary (i.e., short-term) nature of the impact, however, the effect on humans would be self-limiting.

These substantial human effects are considered unavoidable for the reasons listed under their respective impact discussions, as cited above.

3. Significant Cumulative Impacts

A number of impacts have been found to be cumulatively significant, even when individually limited. These cumulatively significant impacts are summarized in Table 5.5-A and described in detail throughout the sub-sections of Section 5.5.C. These cumulative impacts are considered unavoidable because they would result as a consequence of long-term growth within Riverside County and occur in incrementally insignificant but cumulatively substantial stages.

D. Unavoidable Significant Effects Conclusions

For the reasons outlined above and throughout the various parts of Sections 4.0 and 5.0, the future development accommodated by GPA No. 960 pursuant to the updated Riverside County General Plan would be associated with a number of significant, unavoidable impacts. These can be summarized as follows:

A number of unavoidable significant impacts associated with GPA No. 960 would have the potential to degrade the quality of the environment, including: encroachment into or conflict with areas with existing agricultural uses, short-term construction and long-term operational air quality emissions, as well as cumulatively significant project air quality, excessive noise levels and both temporary and permanent increases in ambient noise levels, and provision of roads in conflict with circulation performance standards.

These unavoidable significant impacts would have the potential to curtail the range of the environment: indirect conversion (loss) of designated Farmlands to non-agricultural uses, insufficient water supplies (to assure long-term water availability) and the depletion of groundwater supplies (and resultant overdraft conditions) due to increased use of groundwater in the future.

These unavoidable significant impacts would facilitate the achievement of short-term goals to the disadvantage of long-term environmental goals: provision of county roads, leading to improved traffic flow in some areas while contributing to increases in air pollutants, noise and traffic congestion; actions to obtain additional imported water supplies to meet increasing demands would contribute to potential long-term environmental effects to the natural watersheds normally using the water; similarly, using groundwater to meet local water supply needs could also lead to overdraft of basins without sufficient recharge. And, lastly, growth induced by the project would achieve short-term goals, particularly economic ones, while resulting in adverse effects on the natural environment.

These unavoidable significant impacts would be cumulatively considerable, even though individually limited in most cases: inducement of population growth, adverse effects to scenic vistas, adverse light and glare effects, conversion of designated farmlands to non-agricultural uses, encroachment of new development into areas with existing agricultural uses, short-term and long-term air quality emissions, cumulative project air quality *and greenhouse gas* impacts, exposure of sensitive receptors to air pollutants, *impediment of 2050 greenhouse gas emission reduction*

targets, exposure of people or structures to strong seismic groundshaking, landslides and wildland fires, excessive noise levels, permanent or temporary increases in ambient noise levels, conflicts with circulation system performance and congestion management programs, insufficient water supplies, depletion of groundwater supplies or overdraft, effects to existing recreational resources and permitted landfill capacity, and impacts due to the need for additional stormwater drainage facilities. A number of growth-inducement effects would also be cumulatively significant, even if individually minor. These include: direct and indirect economic growth, population growth and the construction of additional housing.

Lastly, these significant impacts would have the potential to cause unavoidable substantial adverse effects on human beings, either directly or indirectly: exposure of sensitive receptors to air pollutants, including both short-term (construction) and long-term (operational) air emissions, as well as exposure to noise levels in excess of standards, including from both temporary and permanent increases in ambient noise levels. Substantial adverse human impacts would also occur indirectly as a result of safety risks due to potential exposure to strong seismic groundshaking, landslide hazards and wildfires.

Because GPA No. 960 seeks to update the existing Riverside County General Plan, it is unavoidably associated with impacts that would have a significant effect on the environment, as outlined above. Further, due to the nature of the General Plan as a tool for directing appropriate growth within Riverside County over time, these significant impacts are unavoidable. As detailed throughout this EIR, and particularly in Section 4.0, the General Plan seeks to ensure future development anticipated in Riverside County is planned for and accommodated in a manner that minimizes adverse environmental effects to natural resources and human beings within Riverside County and maximizes the conservation and protection of important resources, while at the same time providing the flexibility and organization needed to continue to grow as a county. It is for this over-arching reason, addition to those outlined herein, that GPA No. 960 is being proposed despite these significant and unavoidable effects.

5.2 Significant Irreversible Environmental Changes

A. Introduction

CEQA (PRC) Sections 21100(b)(2) and 21100.1(a) require that EIRs prepared for the adoption of a plan, policy or ordinance of a public agency include discussion of significant irreversible environmental changes resulting from project implementation. The State CEQA Guidelines, CCR Section 15126.2(c), describes "significant irreversible environmental changes" that would be caused by a project as the following:

> *Uses of nonrenewable resources during the initial and continued phases of a project may be irreversible, since a large commitment of such resources makes removal or non-use thereafter unlikely. Primary impacts and, particularly, secondary impacts (such as highway improvement which provides access to a previously inaccessible area) generally commit future generations to similar uses. Also, irreversible damage can result from environmental accidents associated with the project. Irretrievable commitments of resources should be evaluated to assure that such current consumption is justified.*

With the above in mind, the various proposed components of the project, GPA No. 960, were evaluated for their potential to cause or result in significant irreversible environmental changes. It should be noted that unlike standard significance findings for impacts that cannot be reduced through mitigation, a significant *irreversible* change may occur when an action commits "future generations to similar uses," irrespective of any mitigation applied to the specific action. Thus, the following question was analyzed to determine if significant irreversible

environmental changes would be associated with the project: Would the project components do any of the following?

1. Result in a large commitment of non-renewable resources that make later removal or non-use unlikely.

2. Result in the commitment (or consumption) of "irretrievable" (i.e., non-renewable) resources beyond what is justified.

3. Result in primary or secondary impacts that generally commit future generations to similar uses.

4. Result in an environmental accident that could cause irreversible damage.

B. Analysis of Project Components

The various project components of GPA No. 960 were analyzed to assess the likelihood of their exceeding one of the above criteria. The results are grouped by criteria and discussed below. For further details on the specifics proposed for these components, see Section 3.0 (Project Description).

1. Result in a Large Commitment of Non-Renewable Resources

This effect represents a significant irreversible environmental change when it involves the large commitment of resources in a manner that makes their later removal or non-use unlikely. This includes, in particular, the use of non-renewable resources during either construction or operational phases of development.

A non-renewable resource is one that comes from the earth and cannot be readily replenished within the human timescale. This includes mineral resources, particularly aggregate and metal ores, and fossil energy resources, such as oil, coal and natural gas. Aggregate minerals, including rock, sand and gravel, are used extensively in the construction of structures, roads and other infrastructure (particularly canals and other drainage facilities). Related mineral resources are also used to manufacture cement, drywall and other essential building materials. Metal ores are necessary to produce the myriad metals needed for modern life: iron is necessary to make steel, used in everything from penny nails to I-beams to literally the kitchen sink; copper is used extensively for wiring in homes and businesses, as well as in electrical generators, and copper piping is often used for plumbing; aluminum is also used extensively in building construction, as well as for food packaging, in sodas and canned foods; precious metals, such as platinum, gold and silver, are used both for industrial uses, particularly in high-tech devices (cell phones, computers, etc.), as well as for jewelry and artistic works, as are precious stones (industrial-grade diamonds and garnets used for cutting, grinding and polishing, and gem-quality stones used for adornment). "Technology metals," such as cobalt, europium, cadmium, yttrium, gallium, indium, niobium, scandium, erbium, lanthanum and neodymium, plus lithium, are used in the mass-production of miniaturized electronics (including anything with a computer chip), weapons systems and batteries. As an example, every Prius hybrid car carries with it about 10 pounds of lanthanum, as a "nickel-metal hydride," in its batteries. And, of course, uranium is mined and purified for use as nuclear fuel in reactors. Because of their association with energy production, fossil fuels are discussed under the subsequent subsection, below, rather than here, where the emphasis is on ore-based mineral resources.

As outlined in Section 4.14 (Mineral Resources), the State of California uses large, multi-county "Production-Consumption Regions" as their boundaries for study areas for assessing aggregate production capacities and their associated market areas. As part of the classification process, the State of California has calculated both the fifty-year aggregate demand forecast and the amount of aggregate resources available for the given area. Three State

Production-Consumption Regions include parts of Riverside County. This is important, as the mining of aggregate resources located too close to urban or environmentally sensitive areas is often infeasible due to land use conflicts. Yet when located too far away, the cost of transportation (fuel) makes a mineral resource economically non-viable (and indirectly increases production and consumer prices as well). However, as outlined in Section 4.14, analysis indicates that even with the future development outlined under the project, the availability of aggregate resources in Riverside County would still be assured. Sufficient aggregate resources exist or are potentially developable for future use as needed to meet the next 50 years of demand for the region's growth.

As discussed more fully under item *3*, below, the project does not include any actual development proposals. It would, however, potentially enable future development in a variety of areas – increasing development potential in some areas, decreasing the potential in others. Among the project items with a land use component, no refineries, large-scale manufactories or large-scale infrastructure development (i.e., hydroelectric dams, nuclear reactors, wastewater treatment facilities, canals, interstate freeways, etc.) or other massive structures (skyscrapers, penitentiaries, etc.) are proposed or planned which would necessitate the commitment of large amounts of aggregates, including rock, sand, gravel, cement and other minerals to accommodate the project. Road-building, which utilizes large amounts of aggregates, will occur throughout Riverside County as per the countywide circulation network proposed for the updated General Plan. These roads, however, would be constructed incrementally in segments over the next 50 years. Accordingly, demands for aggregate resources would remain relatively consistent over this period, with demand increasing roughly according to county growth rates. As such, demand for aggregate materials would be relatively constant, fluctuating mainly with growth rates and well within the forecast horizons of supply availability for the Riverside County's Production-Consumption Regions. See Section 4.14 for more details on mineral resources.

Similarly, in relation to ores and metals, no foreseeable mining uses, large-scale manufactories, foundries, smelters, high-tech device plants or energy-generation uses, which include wind farms, non-photovoltaic solar farms and other energy plant facilities that would require large amounts of various metals, particularly copper, for use in the motors that ultimately generate the electricity, are proposed or planned which would necessitate the commitment of large amounts of ore or metals in their construction or operation.

In total, none of the items proposed as part of GPA No. 960 would necessitate a large commitment of non-renewable resources in a manner that makes their later removal or non-use unlikely. The project would not result in a significant irreversible change in the environment due to the use of non-renewable resources.

2. Result in the Unjustified Consumption of Non-Renewable Resources

As outlined in Section 4.10 (Energy Resources), energy resources can most broadly be defined as the force that enables work to be done. Most commonly, this force is generated from either electricity (electrons) flowing through a circuit or motor, or from the combustion (burning) of a fuel in an engine. The types of fuel used to run an engine or motor include both renewable and non-renewable sources. For full details on this issue, see Section 4.10. For the purposes of the discussion here, however, non-renewable fuels may be simply defined as those coming from the earth that cannot be replenished on a human timescale. Thus, petroleum (oil), coal, natural gas and the associated materials and byproducts of the pumping and refining of these fuels, collectively "fossil fuels," represent the most common and widely-used non-renewable energy sources.

As mentioned above, a project may be deemed to have significant irreversible changes if it would necessitate the unjustified (i.e., wasteful) consumption of non-renewable resources, in this case, fossil fuels. Future development accommodated by the project would require the consumption of fossil fuels (oil and other petroleum products) to run equipment, such as bulldozers, backhoes, scrapers and other construction equipment, as well as to run manufacturing and other industrial machinery. Oil and other petroleum products would also be used to run

motor vehicles for commuters, personal trips, shipping and transit, aircraft and ship-borne traffic, as well as other types of vehicles (recreational vehicles, forklifts, etc.). Vehicular use represents the largest source of fossil fuel use within Riverside County. Fossil fuels, particularly coal and natural gas, are also used to generate steam to run steam-turbines in the production of electricity by utility providers. Lastly, natural gas, as well as less commonly fuel oil, propane or kerosene, are used to heat and/or cool homes and other dwellings, run boilers and various other industrial and commercial equipment.

Analysis of these energy uses was conducted as outlined in Section 4.10. The results indicate that the project would not result in an excessive (significant) consumption of non-renewable resources. The uses proposed to be accommodated by GPA No. 960 are those necessary to accommodate the continued future growth of Riverside County in an orderly, reasonable manner. As such, none of these uses would be considered "unjustified." Additionally, a variety of policies and plans included in the project would ensure that energy resources (renewable and non-renewable) are used in an efficient and judicious manner. Riverside County's proposed Climate Action Plan, in particular, includes numerous measures to reduce fossil fuel combustion (as a way of reducing greenhouse gas emissions) and improve energy efficiency. See Section 4.7 (Greenhouse Gases) for more details.

In total, the analysis in this EIR indicates that GPA No. 960 would not result in the unjustified consumption of non-renewable resources and would not cause a significant irreversible environmental change as a result.

3. Commit Future Generations to Similar Uses

Another irreversible change is one that commits future generations to similar uses. For the purposes of this EIR, such an environmental change is defined as one resulting in a transformation of the fundamental character of a site such that it would no longer be suitable for certain uses. The most archetypical example of such a change would be the conversion of vacant open space with natural vegetation to an urban or suburban use – such as a tract of homes or a strip of commercial stores, for example. In such cases, the resulting environmental changes would be very difficult to reverse; the cost of reversal combined with the investments already in place make the likelihood of a significant change in use highly unlikely. This type of change can occur through two mechanisms: direct changes, such as development of vacant land, particularly open space; and, secondary changes, such as introduction of roads or other infrastructure that makes a previously undeveloped area more likely to develop.

GPA No. 960 does not propose or include any actual development as part of the project. It does, however, propose changes at the General Plan level that could result in future development of lands, as well as infrastructure, particularly roads and trails. This is most evident in the project components related to land use. In many cases, the project merely proposes to change the land use potential of a site (i.e., through land use designation change) or area (due to a new or revised policy area, overlay or other policy) in a manner that may increase or lessen future development potential on a site either already developed or already proposed for development under the existing General Plan. In these instances, the proposed changes would not cause *new* impacts due to the commitment of future generations to similar uses. Likewise, the various informational item changes proposed in the Safety Element and Multipurpose Open Space Element also would not affect future commitments. Because they disturb such small areas and are typically easily reversible, the new trail alignments proposed in GPA No. 960 also would not be considered a source of significant irreversible change.

Where the proposed updated countywide circulation network plan proposes new roadways alignments in areas previously without roads, however, these could have a potentially significant irreversible effect. Although new roads in and of themselves can have relatively small impact footprints, the growth-inducing effects that often accompany new roads create a whole suite of attendant growth-inducing effects that can collectively result in significant irreversible impacts to previously pristine, vacant open space lands.

Of the land uses proposed (mapped) in the General Plan Land Use Element, a number of parcels are proposed for land use designation (LUD) changes as part of GPA No. 960. In the "real world," the exact timing and location of individual future projects developed pursuant to the updated General Plan are not foreseeable because of the numerous economic, demographic and other factors that influence such decisions. However, for the purposes of this analysis it was assumed that all of the LUD changes proposed in GPA No. 960, as well as all other project land use changes with known spatial components would occur incrementally over the next 50 years. Such an assumption enables theoretical predictions to be made about potential future commitments of resources needed to serve the proposed levels of development.

Future development within Riverside County resulting from the proposed spatial changes included in GPA No. 960 would result in the construction of structures, facilities and infrastructure on lands that are currently undeveloped. Development of lands would generally result in their future and permanent commitment to built uses. Environmental changes associated with future development would occur as the physical environment is altered. Changes to the physical environmental would occur through the continued commitments of land and construction materials to urban and rural development. There would be an irretrievable commitment of labor, capital and materials used in construction, and a permanent loss of open space. Specifically, the project components that are considered to have the potential for committing future generations to similar uses are those that affect lands that would be undeveloped, *but for the proposed change*, and also lands subject to new roadways. In some cases, the project proposed to change LUDs from those with little to no development potential (i.e., OS-C, OS-CH or OS-W) to a developed use (most often rural residential). These are shown in Table 5.2-A (Open Space Areas Proposed for Future Developed Uses), below.

As indicated by the table, a total of approximately 2,784 acres would be committed to significant irreversible environmental changes due to the future development potential on these sites resulting from GPA No. 960. This includes areas denoted by C2-3b, C2-6 and C2-7, totaling roughly 232 acres where the sites are surrounded on all sides by lands designated OS-CH, have native vegetation and no access roads on, abutting or in the vicinity of the parcels. Nine proposed changes (C2-1b, C2-4, C2-5, C2-8B, C2-13b, C2-17b, C2-20, C2-21, C2-22a and C2-23b) totaling just under 2,300 acres would affect lands surrounded by OS-CH areas on at least two sides, with little to no access (sporadic dirt roads, at most), intact or mostly intact native vegetation and only sparse rural and/or agricultural development in the vicinity. And in two areas, denoted by C2-15 and C2-23b, a total of roughly 254 acres are located in areas of generally undeveloped open space in which future development would represent an extension of rural or suburban land uses in the region onto undeveloped lands. Further, this impact would be unavoidable as it results from build out of the General Plan, which would accommodate Riverside County's growth with or without GPA No. 960.

Table 5.2-A: Open Space Areas Proposed for Future Developed Uses

* Denotes existing LUD proposed for change under GPA No. 960, as indicated, if more than one existing OS LUD.
Source: Riverside County Planning Dept., Analysis of Project Data, 2011.

The future development potentially allowed on these sites as a result of the LUD changes proposed under GPA No. 960 would lead either to irreversible change in the middle of vacant, undeveloped land with intact native vegetation and other natural resources, and possibly require further disturbances to provide access, water, sewer collection and other infrastructure, or would represent the extension of an existing general pattern of land use (typically rural or agricultural) into natural open space located on the border between developing areas and natural open space. Once developed, the loss of open space is generally irreversible. The natural biota in a given locale is the result of millennia of evolution. Thus, the ability of humans to fully restore the functions and values of biota and habitat lost to development is limited. Accordingly, to ensure the "worst case" is considered, areas with urban, suburban or rural development potential are considered to be subject to permanent, irreversible effects on the natural communities, plants, wildlife and their patterns of existence in these areas. Because of restoration difficulties, future development of these areas would represent significant irreversible changes in the environment and commit future generations to perpetuating the developed uses that would result.

4. Potential for Accidental Irreversible Damage

Another source of significant irreversible change is from accidents causing irreparable environmental damage. Such accidents could occur through a variety of human activities, including: spill or release of a hazardous material or radioactive substance to land, air or water; accidental fires in wildlands due to human carelessness or inattention, or fires resulting from mechanical or industrial failures (pipe ruptures, airplane or vehicle crashes, etc.); flooding or dam inundation due to failure of a man-made structure for channeling or retaining water (dams,

canals, etc.); or, landslides or mudslides resulting from failure of an engineered slope or soil, or improper hydrological improvements (drainage). While there are many other types of accidents possible, those listed above represent the key sources for irreversible damage that can be associated with the types of future development (i.e., human alterations of the natural environment) to be accommodated by GPA No. 960.

As noted above, the project does not include any actual development proposals. It would, however, alter future development in a variety of areas – increasing development potential in some areas, decreasing the potential in others. As such, it does not include any new proposals for specific uses in which hazardous materials or radioactive substances would be used, generated, stored, processed or shipped. In addition, no new or revised landfill or waste disposal sites are proposed as part of GPA No. 960. Some areas may ultimately be developed as a commercial, industrial or public facility in which hazardous materials are used at some time in the future. However, such locations and uses are not unforeseeable at this time and it is presumed that such risks would also be mitigated by compliance with standard regulatory requirements for the use of hazardous materials. Likewise, for the types of residential, commercial and industrial development that would be accommodated by GPA No. 960, it is assumed that all new uses of hazardous materials would occur pursuant to applicable laws and regulations. That is, commercial or industrial use involving hazardous materials would obtain and comply with a valid materials license specifying the requisite safety measures for the use, handling, storage, transportation and disposal of these materials. See Section 4.13 for more details.

Similarly, while the project would facilitate the extension of development into previously undeveloped areas (as discussed above), these areas are not considered to be of significant increased risk of damage due to wildfire potential. Where new development approval is sought within areas of High Fire Hazard, the various fire fuel modification zone and/or setback requirements would apply. As outlined in Section 4.13, such measures would be sufficient to minimize wildfire threats. Likewise, all new commercial, industrial and public facilities would also be subject to applicable approvals, regulatory compliance and other policies and programs aimed at ensuring the safety of hazardous materials, dangerous substances, electrical equipment and the like are installed and used safely. A variety of fire standards for construction, pursuant to the California Building Code, also would apply to future development.

No new dams or reservoirs are proposed as part of the project. Further, it is assumed that any proposed in the future would be subject to all applicable grading, construction and geotechnical design standards and regulations adopted for the purpose of ensuring such facilities are safely constructed, operated and maintained. This includes strict prohibitions and regulations regarding 100-year floodplains that would also further protect future development from potential flooding risks. See Section 4.11 (Flood and Dam Inundation Hazards) for details.

Lastly, with no specific development proposals included in GPA No. 960, the locations and specifics of future slopes, cut and fill excavation, and other soils engineering activities, as well as future drainage plans and hydrology changes, cannot be foreseen at this time. It is assumed, however, that all future development, including excavation, compaction, grading, construction of structures, roads, drainage facilities, slopes, landfills, pads, foundations, piers and numerous other activities, would all be subject to the extensive local, state and federal regulations, building codes and geotechnical standards enacted to ensure that such uses do not result in a geotechnical, soil or slope hazard. See Section 4.12 for additional information.

In total, for all of the above reasons, the changes associated with GPA No. 960 would not result in a significant risk for an accident or upset that would cause irreversible environmental damage.

C. Conclusion on Irreversible Changes

In total, the analyses presented in this EIR indicate that none of the items proposed as part of GPA No. 960 would necessitate a large commitment of non-renewable resources in a manner that makes their later removal or non-use unlikely. The analysis also found that future development accommodated by GPA No. 960 would not be expected to result in the unjustified consumption of non-renewable resources. And, in addition, the changes associated with GPA No. 960 would not result in a significant risk for an accident or upset that would cause irreversible environmental damage. This includes accidents associated with a variety of human activities, including: spill or release of a hazardous material or radioactive substance to land, air or water; accidental fires in wildlands due to human carelessness or inattention, or fires resulting from mechanical or industrial failures (pipe ruptures, airplane or vehicle crashes, etc.); flooding or dam inundation due to failure of a man-made structure to properly channel or retain water; or, landslides or mudslides resulting from failure of an engineered slope or soil, or improper hydrological improvements (drainage).

The future development potentially accommodated in some locations as a result of the LUD changes proposed under GPA No. 960 would, however, lead to irreversible changes in the middle of vacant, undeveloped land with intact native vegetation and other natural resources, due to development and possibly the need to provide access, water, sewer collection and other infrastructure. In other areas, it would result in the extension of an existing development pattern (most typically rural or agricultural) into open lands lying on the border between developing areas and native open space. Because of the difficulty in restoring previously untouched areas to fully functional natural resource values, including biological, hydrological, geological, in addition to edge effects, the future development of these areas would represent significant irreversible changes in the environment and likely commit future generations to perpetuating the resultant developed uses. Introduction of roads into previously inaccessible areas would have a similar effect. Although roads in and of themselves can have relatively small impact footprints, in some cases the growth-inducing effects that accompany such roads (due to opening access to new areas) create a whole suite of attendant effects that can collectively result in significant irreversible impacts to previously untouched, vacant open space lands.

The individual environmental effects of future development in specific locations are addressed and, in many cases mitigated to less than significant levels, in the respective parts of Section 4.0. However, notwithstanding these mitigation measures, the irreversible nature of the effects to natural open space areas would remain significant due to their essentially irreversible nature. This effect is a cumulative outcome would result from the build out of the General Plan, both the existing General Plan and for the updated General Plan, as proposed pursuant to GPA No. 960. As such, the policies and programs outlined in the General Plan itself, as well as the proposed Climate Action Plan, EIR No. 521 and existing EIR No. 441, which was certified for the 2003 adoption of the RCIP General Plan, provide a suite of measures that mitigate the effects of continued county growth. However, no other specific mitigation measures are feasible with regard to this effect. As such, this impact would remain significant and unavoidable.

5.3 Significant Effects on Humans

As mentioned in Section 5.1, a number of environmental effects associated with the project, GPA No. 960, have the potential to result in "environmental effects which [would] cause substantial adverse effects on human beings, either directly or indirectly." (State CEQA Guidelines, Appendix G, XVIII.c.)

The project would have a wide range of effects on human beings. Of these impacts, a handful would rise to the level of resulting in "substantial adverse" human effects due to their degree of individual effect, their cumulative

effect or their unavoidability. The majority of these human impacts arise indirectly from cumulatively substantial effects. Two would occur as a direct result of the project, as summarized below. These substantial human effects are considered unavoidable for the reasons listed under their respective impact discussions, as cited below. For further details on a given impact, see the respective environmental impact and section listed.

A. Air Quality

As described under Impacts 4.6.B(1), 4.6.B(2), 4.6.C and 4.6.D in Section 4.6, future development accommodated by GPA No. 960 would expose sensitive receptors (i.e., people with sensitive respiratory tracts) to pollutant emissions, including from potentially significant short-term (construction) and/or long-term (operational) activities, depending on the location. The degree of impact would depend on the type of operation, distance from sensitive receptors and the level of activity at each site. If a human was located within close enough proximity to a source of pollutants exceeding regulatory standards, for example from a construction site or an industrial operation, such an exposure could result in a significant impact to the human. In addition, as the exact location, timing and level of future development activities arising from GPA No. 960 is unforeseeable, specific impacts to sensitive receptors cannot be quantified. As a result, this EIR cannot guarantee (even with the incorporation of all feasible mitigation measures) that pollutant levels would be able to be reduced to below applicable agency thresholds. Thus, per Impact 4.6.D, impacts associated with exposure of sensitive receptors to air pollutants would be significant and unavoidable.

Sensitive populations include children, the elderly, the acutely ill and the chronically ill, especially those with cardiorespiratory diseases. In terms of land use, sensitive receptors are areas where sensitive populations may be for extended periods of time, resulting in sustained exposure to any pollutants present. As mentioned in Section 4.6.4, localized significance thresholds (LSTs) have been developed by the SCAQMD to determine maximum allowable concentrations of criteria air pollutants during construction and operation of a project. Data in Section 4.6 indicate that it is possible to adequately mitigate or avoid certain construction emissions (e.g., CO, NO_X, and $PM_{2.5}$). However, however for PM_{10} the construction activities would need to be a minimum of 50 meters from the nearest sensitive receptor in order to be less than significant. For future development sites where this distance cannot be achieved, a significant impact would result.

In addition to criteria pollutants, localized emissions of toxic air contaminants (TAC) are also of concern with respect to sensitive receptors. Sources of TACs include diesel particulate matter from railroads, emissions from the combustion of airplane fuel, benzene emissions in close proximity to gasoline dispensing stations, dry cleaners and film processing services that use perchloroethylene, auto body shops due to various solvents, furniture manufacturers and repair facilities that use methylene chloride and print shops that use various solvents. However, the primary source of TACs within the County of Riverside is from diesel-fueled trucks and other vehicles using the freeways and major roadways throughout Riverside County. Guidance from the California Air Resources Board (CARB) calls for buffer zones to insulate sensitive receptors from TAC sources. This is feasible and effective mitigation where land use patterns allow. However, where such distances are not achievable, residual impacts would remain significant and unavoidable. Because of increased densities proposed for various land uses in Riverside County and the desire for proximity of residential land uses to both transit and commercial centers, it can be assumed that both construction and operation of commercial and industrial sources could be developed relatively close to sensitive receptors, such as residences or schools. For these reasons, the effects of project emissions on sensitive receptors (i.e., certain populations of humans) throughout Riverside County would be significant and unavoidable.

B. Geology and Soils

Like all of Southern California, Riverside County has experienced and will continue to face groundshaking resulting from activity on local and regional faults. As outlined in Impact 4.12.B (Section 4.12.6), future development consistent with GPA No. 960 would result in the potential for adverse effects to humans, including injury or death, resulting from this groundshaking hazard. As outlined in Section 5.5, this impact would be individually insignificant due to regulations prohibiting construction on faults, as well as requiring setbacks and various structural engineering measures. Thus, the risk is largely mitigated for new development by required structural engineering standards that would apply to new development. However, the growth-inducing effects of GPA No. 960 would also mean that more people would be introduced into Riverside County, thus increasing the number of people subject to risks from structures that may not meet the most-current seismic standards. Accordingly, a major earthquake along one of the major faults in Southern California could have the potential to substantially affect humans through injury or even death.

For similar reasons, the project could also result in a substantial adverse effect to people as a result of landslides. As outlined for Impact 4.12.D (in Section 4.12.6), landslides and rockfall can occur throughout Riverside County as a result of seismic activity and other natural processes, as well as resulting from human activity. Future development within Riverside County accommodated by GPA No. 960 would increase the potential for structures and facilities in areas susceptible to landslides or rockfall. Compliance with existing laws and General Plan policies would reduce potential landslide and rockfall impacts for new development to less than significant levels. However, on a cumulative basis, growth would also result in an increase in the number of people living, working and visiting within Riverside County. Where these people would be exposed to unmitigated landslide risks (such as non-conforming structures, structures located in areas of known [mapped] rockfall hazards and people recreating in natural areas prone to rockfall, for example), potentially substantial effects to humans, including injury or death, could occur.

C. Fire Hazards

As outlined for Impact 4.13.H (in Section 4.13.6), areas of high fire hazard exist within unincorporated portions of Riverside County, including rural, mountainous terrain, as well as areas adjacent to, or covered by, natural grasslands or brush. GPA No. 960 would accommodate future development in previously undeveloped areas, including some with high or very-high fire hazards. This would increase both the number of people and amount of property potentially exposed to fire hazards. Additionally, there is the potential for an increase in the occurrence of fires, particularly in urban-wildland interface areas, due to increasing human encroachment. Compliance with existing regulations and General Plan policies would be sufficient to ensure that this impact is less than significant for new development resulting from the project. However, as with the other safety hazards, growth occurring in Riverside County over time would expose humans to indirect fire hazards. In particular, wildfire risks to humans could occur where county growth introduces more people to areas with high wildfire hazard potential, particularly in rural areas and adjacent to natural areas, and in existing structures that may not conform to current fire codes. This indirect impact is an unavoidable cumulative effect of growth leading to an increased number of people in areas of wildfire hazard and increased potential for human-caused wildfires due to increased human encroachment into wildlands.

D. Noise

As outlined under Impact 4.15.A (in Section 4.15.6), future development accommodated by GPA No. 960 would incrementally increase rural, suburban and urban uses in localized areas throughout unincorporated Riverside County. In some locations, this would result in the introduction of new noise-sensitive land uses into areas of

existing excess noise or areas in which county growth would eventually lead to excess noise levels. In addition, future development accommodated by GPA No. 960 would contribute incrementally to increased traffic volumes on county roads, resulting in noise increases affecting sensitive land uses along existing and future roads. As a result, new development, particularly residential uses along and adjacent to major transit corridors, could be exposed to noise levels that exceed Riverside County's noise standards. Existing sensitive uses (and the humans occupying them) would also be subject to these higher noise levels. Compliance with existing noise standards, regulatory programs, General Plan policies and existing mitigation measures from EIR No. 441 would reduce the effects of noise on new development to less than significant levels. However, where noise generators would expose existing receptors (residences and other sensitive uses) to excessive noise, impacts on humans would be significant and unavoidable, as mitigation of these incremental and wide-spread noise impacts is infeasible. Thus, in some locations, noise generated as a result of the project (either directly or cumulatively) would result in a substantial adverse effect on humans.

As noted above, the source of these substantial noise effects on humans would be either construction or traffic activities. Operational activities, in particular motor vehicle operations, would result in substantial permanent ambient noise level increases in specific areas. Construction activities would result in substantial temporary ambient noise level increases. These two impacts are delineated under Impacts 4.15.C and 4.15.D, respectively. The excessive permanent noise levels would adversely affect people where such long-term exposure is above the acceptable noise levels established in various County of Riverside and State of California noise standards. The cumulatively substantial and unavoidable temporary noise increases would also affect people where such exposure is above the acceptable noise levels established in various County of Riverside and State of California noise standards. Due to the temporary (i.e., short-term) nature of the impact, the effect on humans would be self-limiting. Nevertheless, however, human effects could be substantial over the short term.

E. Circulation and Traffic

As outlined under Impact 4.18.A (in Section 4.18), future development accommodated by GPA No. 960 would incrementally increase rural, suburban and urban uses in localized areas throughout unincorporated Riverside County. This new development would result in an increase in traffic levels both on existing and newly constructed county roads. In general, new roads and existing road improvements associated with new development are required to provide appropriate pedestrian and bicycle access routes. These routes vary in their level of development depending on the nature of the project triggering their implementation. The General Plan Circulation Element outlines the standards for a variety of pedestrian, equestrian and bicycle lanes. In some cases, new facilities would be introduced in locations isolated from other existing pedestrian/bicycle routes. In other cases, existing routes may be available, but insufficient, intermittent or substandard. When this occurs, the potential exists for safety impacts to humans to result. As outlined in Section 4.18, however, compliance with existing trail standards, General Plan policies and existing mitigation measures from EIR No. 441 would ensure the effects of new development on non-vehicular transportation, and hence humans the using these facilities, would be less than significant.

Section 5.4 Growth Inducement

Pursuant to Section 151 26.2(d) of the State CEQA Guidelines, this EIR includes a discussion of "the ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment." Also according to this same regulation, growth-inducing projects include those that would "remove obstacles to population growth." It also notes that, "increases in population may tax [i.e., strain] existing community service facilities, requiring construction of new

facilities that could cause significant environmental effects." And, lastly, it states that, "the characteristics of some projects...may encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. It must not be assumed that growth in any area is necessarily beneficial, detrimental or of little significance to the environment."

Accordingly, an analysis was performed to determine if any of the components of the proposed project, GPA No. 960, could foster, either directly or indirectly, economic growth, population growth or the construction of additional housing. Direct growth inducement includes actions that would lead to an increase in the number of homes, jobs, people or economic transactions. Among other things, direct growth inducement may occur through direct development, including encroachment onto isolated or remote lands, diminishment of open space or leapfrog development. Indirect growth inducement can occur through a precedent-setting action or when an impediment to growth is removed. Most commonly, indirect growth is associated with the provision or extension of essential public services. A classic example is the development potential that arises when infrastructure, in particular roadways and potable water services, are extended into new areas. A precedent-setting policy change that removes an obstacle to growth, for example the establishment of a land use overlay that accommodates a set of alternate, more urban land use designations, would also be an example of indirect growth inducement. Lastly, economic expansion can itself be an indirect source of growth inducement by drawing to an area people wishing to take advantage of the additional jobs or housing that result.

A. Growth Assessment Factors

As part of this EIR, the proposed components of GPA No. 960 were assessed for their growth-inducement potential. From the above CEQA information, the following questions were developed. Would the components of the project do any of the following:

1. Foster direct or indirect economic growth.
2. Foster direct or indirect population growth.
3. Result in construction of additional housing.
4. Remove obstacles to population growth.
5. Encourage or facilitate other activities leading to significant environmental effects, including encroachment into isolated or remote areas.
6. Result in population increases that may strain community services or facilities.

These issues can be generally evaluated qualitatively for many of the project's components. For those items with spatial components, however, a further set of specific demographic standards were developed to enable assessment of the relative potential for significant growth inducement for each. A project component would be considered growth inducing if it would do any of the following:

Standard for Fostering Additional Housing: For the purposes of this analysis, a project component was defined as "fostering additional housing" if it would lead to an increased number of dwelling units at build out. As per the procedures and factors in Appendix E-1 of the General Plan, for each area of residential land use designated under GPA No. 960, the theoretical number of dwelling units expected to be accommodated by the site at build out was calculated. The total expected was then compared to the overall total expected within the Area Plan in which the proposal was located. A project component was deemed "significantly" growth-inducing

if it would increase the expected number of dwelling units present by more than the annual growth rate projected for Riverside County by the Riverside County Center for Demographic Research (RCCDR); that is greater than 3% of the Area Plan's total. Development potential resulting in one-tenth of a percent (0.1%) or less were deemed negligible. And, values between 0.1% and 3.0% were deemed growth-inducing, but not significant.

Standard for Fostering Economic Growth: For the purposes of this analysis, this was defined as increasing the square footage or acreage of land uses most closely associated with economic transactions. Specifically, this meant commercial and industrial uses (CR, CT, CO, BP, LI and HI) which would generate sales taxes, business taxes, and other such economic factors. Similarly, agriculture and mining uses are also included in this definition, particularly as they are associated with additional production and/or processing. Thus, a project component was deemed "significantly" growth-inducing if it would increase the amount of commercial, industrial or agricultural uses (within the respective Area Plan) by 3% or more at General Plan build out with the project component, as compared to build out without the component. Development potential resulting in 0.1% or less were deemed negligible, and values between 0.1 and 3.0% were deemed growth-inducing, but not significant.

Standard for Fostering Population Growth: From a demographic stand point, population growth occurs when the number of people born in or moving to an area exceeds the number of people dying in or moving out of an area. Examined at the programmatic General Plan level, however, population growth is assessed relative to two land use-related factors. First, and most simply, the greater the number of homes in an area, the more people that can be expected to live there. The process by which houses are directly correlated to population is outlined in the methods and factors of Appendix E-1 of the General Plan. And, in the practical sense, this metric is captured by the "fostering additional housing" factor outlined above. Secondly, on a programmatic basis the Riverside County General Plan can only address population growth in terms of attracting people to Riverside County. In addition to offering a low cost of living, e.g., through affordable housing, jobs are a key factor in attracting people to an area. Thus, employment-generating land uses (specifically, CR, CT, CO, BP, LI or HI land use designations) were used as a third metric for assessing growth inducement. The amount of employment-related building square footage planned for an area can be used to directly approximate the number of jobs available, as per the methods and factors outlined in Appendix E-1 of the General Plan. Thus, a project component was deemed "significantly" growth-inducing if it would increase jobs within an Area Plan by 3% or more at General Plan build out with the project component, as compared to build out without the component. Changes resulting in an increase in jobs of 0.1% or less were deemed negligible, and increases of 0.1% to 3.0% were deemed growth-inducing, but not significant.

Standard for Encroaching into Isolated or Remote Areas: CEQA mentions this factor as growth inducing when it necessitates a "major extension of infrastructure" into an area. Thus, for the purposes of this analysis, a project component was defined as growth-inducing via encroachment if it would: result in development (residential, commercial, industrial or public facilities) of vacant, generally undisturbed (i.e., not previously developed) land; be located in an area with limited or no vehicular access (i.e., either no roads or only dirt roads on, through or abutting the site); and, occur in an area not served by an existing water agency and without known groundwater availability (i.e., an underlying groundwater basin). If all of these factors were present, without any mitigating factors, the project component was be deemed "significantly" growth inducing. Aerial photos and GIS data (water district boundaries, groundwater basins, etc.) were used in assessing the criteria.

Standards for Removing Obstacles to Population Growth, including Precedent Setting Actions: This category of growth inducement includes several items. First, it addresses policy changes that would result in the removal of an impediment to growth; that is, changes that would accommodate growth where previous regulatory conditions or limitations prevented or hindered it. An example of this would be the changing of a land use designation from Open Space-Conservation, which severely restricts development, to Medium Density Residential, which allows 3-5 homes per acre. A second example would be actions that establish or result in the

provision of an essential public service; e.g., expanding water or sewer service (or district) into an area without it. In some cases, the proposal of new roads in Riverside County's circulation network can also fall into this category. Lastly, actions which would serve to "encourage or facilitate other activities" causing or resulting in significant environmental effects would themselves be deemed growth inducing. An example of this might be construction of a casino in a remote area, which though mitigated for its own effects, could lead to new surrounding development that results in environmental impacts of their own. The significance of these factors as growth-inducing was determined by the degree to which the altered factor was serving to prevent, limit or impede potential development or utilization of an area. See analysis that follows.

Strain Community Services or Facilities: Lastly, an action or activity that results in the use of existing services or facilities to the point that new ones are necessary may be deemed growth inducing. Similarly, an action or activity triggering the need for new services or facilities in an area previously without such would also be found growth inducing. In this case, the impact refers to the effects of such usage on the human beings using them, rather than directly on the physical environment. (The directly-related environmental effects are addressed separately in the respective sections of the EIR. See Section 4.0, in particular Section 4.17 (Public Facilities), for details.) This effect was generally deemed to be significant if, "but for this action," new services or facilities would not be needed in the affected area.

B. Factors Mitigating Growth Inducement

The above standards set clear guides for determining when an impact would be significantly growth inducing. However, it must be remembered that frequently more than one factor is at work for a given parcel of land or policy proposal. Sometimes a combination of factors may serve to offset each other. As an example, a proposed new business park may increase the number of jobs in an area, perhaps even significantly (more than 3% for the overall area). But, if the site was previously slated for new homes, by committing the land to future employment uses instead, the additional population of the area would be reduced. As a result, the number of schools and parks needed to serve those residents would also be correspondingly lessened.

Since GPA No. 960 proposes a wide variety of land use, environmental and policy changes, in order to assess any one project component, it is necessary to examine the component's effect on the larger area. Specifically, this was done by examining the effect of the component on projected build out of the associated Area Plan. Thus, a proposed change that increased the number of jobs on a site by several hundreds or thousands might only represent only an overall increase of 0.5% in employment within the Area Plan. As such, in the programmatic context of the updated General Plan resulting from GPA No. 960, the change would not be considered significantly growth inducing.

In the final analysis, although specific quantitative factors may be associated with a given project component and may, in fact, even be growth-inducing individually, the ultimate determination of whether or not a change would be significantly growth-inducing must also include the various qualitative and regional factors at work. This is particularly true for the proposed changes involving policies that are not land use-related. Accordingly, in the analyses below, an effort was made to present both the quantitative and qualitative factors that were considered in determining the ultimate level of significance for each of the proposed components of GPA No. 960.

C. Analysis of Project Components

Each of the following project components below was analyzed according to the above criteria. The factors considered in making the significance determinations for each of the project components are also addressed. For further details on the specifics proposed for these components, see Section 3.0.

1. Incidental Rural Commercial Policies

This proposal would enable the approval of small-scale commercial uses within the Rural and Rural Community Foundation Components, uses previously not allowed under these Foundations. Thus, this proposal removes an impediment to growth within the Rural and Rural Community Foundations. This proposal would serve to increase the amount of (retail) economic activity within rural areas, as well as provide a corresponding increase in jobs to staff the new uses. However, this increase was deemed less than significant at the countywide level because of the specific conditions included in the proposal to ensure the uses are developed appropriately (including strict limits on location and size of retail development). In addition, the driving factor behind the introduction of these incidental rural uses would be existing demand in under-served areas, nearly the opposite of growth inducement. For all of these reasons, this proposed project component was found to be growth-inducing, but not a significant source of growth within Riverside County.

2. Sphere of Influence Policy

This proposal is generally growth inducing because it removes an impediment to growth by permitting the General Plan to be amended on a quarterly basis, rather than limiting it to the eight-year cycle established pursuant to the Certainty System in the General Plan's Administration Element, for specific types of infrastructure development. This change provides flexibility needed to allow the County of Riverside and affected cities to coordinate development and infrastructure within their spheres of influence. However, because the policy only applies to areas within city spheres of influence and under closely delineated circumstances related to infrastructure needs, this policy proposal was found to be growth-inducing, but not a significant source of growth within Riverside County.

3. Airport Land Use Compatibility

This project component includes revisions to reflect updated Airport Land Use Compatibility Plans (ALUCPs) within or affecting portions of unincorporated Riverside County. In particular, this includes specific changes to General Plan land use designations (LUDs) for areas surrounding the Riverside Municipal, Flabob and Blythe Airports to ensure consistency with the respective ALUCPs. (See Section 4.13 for further details on these three airport areas.) The general text and map changes made to reflect the ALUCPs were deemed to be generally not growth-inducing. The changes merely reflect existing safety and other airport-related conditions on and around the airports. Further, due to issues beyond the scope of this EIR, even with the changes proposed by GPA No. 960, the General Plan would still have land use consistency issues within the Airport Influence Areas for the Jacqueline Cochran Regional Airport (formerly the Desert Resorts Regional Airport), French Valley Airport and Bermuda Dunes Airport. Within these areas, significant impediments to development remain which serve to hinder growth inducement. For the three airports with specific LUD changes, they were analyzed and deemed to have the following growth-inducing effects, as follows.

Blythe Airport: GPA No. 960 includes LUD changes within the vicinity of this airport to further ensure the safety of the area's residents and visitors. In the most general sense, revising land uses to be consistent with the airport's ALUCP serves to remove an impediment to development. Quantitative evaluation of the proposed LUD changes indicate that the result would yield the potential for an additional 130 or so dwelling units through an offsetting of more widespread low- and medium-density housing near the airport with medium-high and rural densities of housing located farther from the airport, as well as a loss of roughly 130 acres of potential Business Park development. Overall, however, this increase in dwelling units represents only a very small proportion (1.4%) of the total units planned for the Palo Verde Valley Area Plan in which the Blythe Airport and its unincorporated surroundings are located. The expected population would increase by a similar small amount. As a

result, though associated with a slight increase in growth, this project component was found not to be significantly growth inducing.

Flabob Airport: Similarly, GPA No. 960 includes LUD changes within the vicinity of this airport to further ensure the safety of the area's residents and visitors. In the most general sense, revising land uses to be consistent with the airport's ALUCP serves to remove an impediment to development. Quantitative evaluation of the proposed LUD changes indicate that overall the number of dwelling units allowed in the region would be greatly reduced (by nearly 900 units). The amount of retail floor space would also be slightly decreased, though the number of jobs would be slightly increased. Overall, however, this slight increase would not significantly affect the Jurupa Area Plan in which the Flabob Airport and its surroundings are located. As a result, this project component was found to have only negligible, insignificant effects on growth.

Riverside Municipal Airport: Lastly, GPA No. 960 also includes LUD changes within the vicinity of this airport. The proposed revisions would remove an impediment to development. Quantitative evaluation of the proposed LUD changes indicate that the overall result would be a decrease in the number of dwelling units allowed in the region. Retail uses and the number of jobs expected in the area would be virtually unchanged. Overall, the changes would not induce growth within the region and this project component was found to have only negligible, insignificant effects on growth.

4. Day Care Facilities

The minor text, policy and procedure changes reflected by this project component would improve the coordination and execution of day care facility planning and review. These changes only clarify existing policies and apply to a specific type of use that occurs only on very small, widely scattered locations across Riverside County. As such, they were found not to have any effect on growth or growth inducement within Riverside County.

5. Open-Space Land Use Designations

This proposal would allow processing of lands into the Open Space Foundation as an entitlement/policy amendment, thus facilitating the preservation of open space dedicated for conservation. It removes an impediment to open space conservation, rather than growth. Thus, this item would not induce growth.

6. Chocolate Mountain Aerial Gunnery Range

This item proposes changes to address land use compatibility, noise and safety issues for the portion of the Navy's Chocolate Mountain Aerial Gunnery Range located within unincorporated Riverside County. As a result, it actually limits development and growth potential. As such, this item would not induce growth.

7. Rural Village Overlays and Study Areas

In the existing General Plan, several rural areas were earmarked for potential urbanization over time via individual "Rural Village" overlays. Or, where the need and location for such urbanization had yet to be determined, Rural Village Study Areas (RVSAs) were created. As part of GPA No. 960, both countywide and area-specific Rural Village policies and plans were evaluated to determine if they remain appropriate as locations for future intensification and whether they provided the necessary implementation guidance. The proposed General Plan policy changes that would apply to all of Riverside County's Rural Village Overlays and Study Areas (i.e.,

proposed Policies LU 34.1-34.6) clarify and refine the existing policies. As such, they would not induce significant growth themselves. In addition to general policy revisions, changes were also proposed for specific Rural Villages, as follows:

Chiriaco Summit: The proposed changes to the existing Chiriaco Summit Rural Village Overlay (RVO) merely clarify existing text and update a map. They do not add or reduce any growth impediments, nor make any changes that would increase the growth potential of the area. For these reasons, it was determined that this project component would not affect or induce growth within Riverside County.

El Cariso Village: As described in Section 3.0, it was determined that a Rural Village Overlay would not be appropriate for El Cariso Village. Thus, GPA No. 960 includes the elimination of the Rural Village Study Area covering the area. As a result, the area would not be subject to potential future development intensification (growth). Rather, the area would merely develop according to the existing General Plan LUDs already established. Hence, it was determined that this project component would control (limit), rather than induce, growth in this region.

Meadowbrook: As part of the General Plan update process, it was determined that this community was suitable for future intensification as it is surrounded by incorporated cities and has the infrastructure capacity to accommodate additional growth. Thus, under GPA No. 960 the existing Rural Village Study Area would be replaced with a full Land Use Overlay (RVLOU) covering roughly 626 acres. Within this overlay, the General Plan would provide policies and mapping accommodating development of alternate, more intense land uses through entitlement. Because the new RVLUO would provide an alternative land use development scenario for this area, it serves to remove a regulatory impediment to growth. Further, the higher intensity uses allowed by the Overlay would foster both economic and population growth in the area, a roughly 9% increase in the Elsinore Area Plan's population and housing, as well as 14% increase in employment and revenue-generating uses (i.e., commercial, industrial, etc.). Given the proposed size of the Rural Village Overlay, this project component would result in significant growth inducement within the Elsinore Area Plan.

Good Hope: The existing Good Hope Rural Village Study Area is located along State Highway 74 and encompasses a variety of existing commercial and light industrial uses. Review also determined that additional urbanization would be appropriate for this community, given the surrounding growth occurring. Thus, GPA No. 960 proposes to create the Good Hope Rural Village Land Use Overlay on a total of 217 acres to provide an alternative land use development scenario for this area. The Overlay would allow higher intensity uses than those of the underlying LUDs, thereby removing an impediment to future growth in the area. Within the Mead Area Plan in which it is located, the Good Hope RVO would result in an increase of roughly 3% more homes and people, and 4% more jobs and economic opportunities. This change is a small, but significant, source of growth inducement for the region.

Aguanga: As part of the General Plan update effort, the existing Aguanga Rural Village Overlay Study Area was reviewed, and it was determined that due to limited access and infrastructure capacity, intensification of the area via Rural Village Overlay was inappropriate at this time. Thus, GPA No. 960 proposes to eliminate this Study Area, allowing it to instead continue to grow according to the underlying LUDs depicted in the General Plan. The removal of this RVSA serves to reduce the future development potential of the area. It would limit, rather than induce, growth in this region.

Anza Valley: Similarly, after review of the existing 1,300-acre Anza Rural Village Overlay, it was determined that a formalized Rural Village Land Use Overlay was not appropriate for this region at this time. Thus, GPA No. 960 proposes to eliminate the existing Rural Village Overlay, allowing the community to instead continue growing according to the underlying LUDs depicted in the General Plan. In addition, a larger area (approximately 71,000

acres) along State Highway 341 was placed within a Policy Area associated with the Anza Valley Municipal Advisory Committee's (MAC) "Goals and Vision" statement. These two steps would limit the area's growth potential, deemed appropriate due to the limited infrastructure capacity, particularly its lack of assured water supplies, and would also ensure coordination of any future development that does occur. For these reasons, this project component would not induce significant growth in the area.

Sky Valley: After review, it was determined that no change was necessary for this Rural Village. Thus, although originally scheduled for updating, GPA No. 960 does not include any changes to the Sky Valley Rural Village Overlay and would not induce growth in this area.

8. Lake Elsinore Environs Policy Area (Lakeland Village)

The 234-acre existing Lake Elsinore Environs Policy Area was reviewed and revised to establish updated land use intensities to reflect revised flood mapping for the Lakeland Village community surrounding Lake Elsinore. Before revision, many properties in the village had "split" LUDs (i.e., two on one parcel or block of land) due to the 100-year flood hazard zone. As part of GPA No. 960, these parcels' LUDs were revised to reflect the changes made to the 100-year flood zone surrounding Lake Elsinore by the U.S. Army Corps of Engineers and the Riverside County Flood Control and Water Conservation District. The proposed changes to roughly 300 acres in and around the Policy Area would remove impediments to development through changes to commercial-retail, residential and open space designations, and, in particular, the removal of split designations (two LUDs on a single parcel). The LUD changes would only slightly increase the number of homes and residents expected in the area. It would also slightly decrease the number of jobs and square footage of economic uses associated with the area. Thus, although this component would result in the removal of a development impediment within the community, the overall potential for it to induce growth would be negligible and insignificant.

9. Northeast Business Park Overlay

The proposed roughly 260-acre Northeast Business Park Overlay would provide an alternative land use scenario for this area, allowing the predominantly agricultural dairy (AG) existing uses to develop as a future business park (BP) if or when urbanization pressure makes such development appropriate. Because this project component would allow an urbanized use (BP) to develop where not previously planned, this item is growth inducing. It would foster direct economic growth in the region. Relative to the Lakeview/Nuevo Area Plan in which it is located, this project component would result in increases of roughly 26% and 16%, respectively, in jobs and commercial/industrial square footage. As a result, this project component would result in significant growth inducement for the region.

10. San Jacinto Agriculture/Potential Development Special Study Area

As part of the General Plan update, it was determined that the nearly 7,700-acre San Jacinto Agriculture/Potential Development Special Study Area was not ripe for development intensification. Accordingly, GPA No. 960 proposes to eliminate the Study Area and let the region remain agricultural (AG). The historically agricultural region would not be subject to a potentially growth-inducing overlay. As such, the project component would serve to limit, rather than induce, potential future growth in the region.

11. Conservation Land Mapping Changes

As part of GPA No. 960, nearly 15,000 acres previously acquired for permanent conservation as habitat under the Western Riverside County Multi-Species Habitat Conservation Plan (WRC-MSHCP) would be designated as Open Space-Conservation Habitat (OS-CH). As a result, future growth potential on these lands would be severely restricted. Thus, this project component would reduce, rather than induce, growth potential within Riverside County.

12. Categorical County-Initiated LUD Changes

As outlined in Section 3.0, GPA No. 960 includes a variety of proposed parcel-specific LUD changes. These changes were grouped according to eight basic criteria. The potential for growth inducement for each of these eight categories are discussed individually, below.

Criteria 1 - Technical Mapping Errors, Including Rural-Mountainous Designations: This category addresses parcels that were erroneously designated as Rural Mountainous (RM), even though they do not meet the steep slope requirements. It also includes mechanical mapping errors. It proposes to affect roughly 80 acres of Riverside County. The reassignment of LUDs from Rural-Mountainous (RM), which limits development due to steep slopes, to other, less restrictive LUDs would technically serve to induce growth. However, analysis of the parcels involved indicates the resultant increase in development potential resulting from the proposed changes would be small. Thus, these changes would not result in significant inducement of growth. It would encroach only minimally into isolated or remote areas.

Criteria 2 - Open Space-Conservation Habitat Designation Changes: This category corrects the LUDs for privately owned lands erroneously designated as "Open Space - Conservation Habitat," (OS-CH), which is normally used to designate publicly held conservation lands. It affects a total of approximately 3,260 acres of Riverside County. See the summary presented in Table 5.2-A for the land use changes, locations and acreages associated with these changes. As with the first category, the reassignment of LUDs from OS-CH, which allows virtually no development to protect biological values, to other, less restrictive LUDs would serve to induce growth. However, analysis of the parcels involved indicates that the resultant increase in development potential resulting from the changes would be small on an incremental parcel basis. Correspondingly, these individual parcel changes alone would not result in significant growth inducement.

However, some of the parcels at issue are located on vacant lands within intact natural habitat and with no existing or planned infrastructure availability nearby, particularly roads, electricity and water supplies. As such, the increased development potentials proposed for these parcels represent a substantial encroachment into isolated or remote lands, because they would necessitate the concomitant extension of roads, utilities and other infrastructure improvements into these open space areas as well. Specifically, sites C2-3b, C2-6 and C2-7b (roughly 232 acres total) are located on undisturbed parcels of native vegetation and surrounded by OS-CH lands on all four sides. Sites C2-1b, C2-4, C2-5, C2-8b, C2-13b, C2-17b, C2-20, C2-21, C2-22a and C2-23b are located on vacant, vegetated lands totaling 2,180 acres and have lands designated OS-CH bordering at least two sides. Lastly, sites C2-15 and C2-23 totaling 254 acres would also extend development into vacant lands. These sites are all located in the far eastern desert region of Riverside County, outside of any existing Area Plan. Statistically, when evaluated against the total area, these small growth-inducing changes would be less than significant relative to overall growth of the far eastern desert region. However, because they would permit development of nearly 3,800 acres of vacant natural lands (predominantly desert scrub habitat) located near, adjacent to, or in some cases even in the middle of, lands designated OS-CH being maintained for their natural conservation functions and values,

the extension of roads, utilities or homes into these areas would represent significant growth-inducing effects, as well as significant irreversible changes to the natural environment.

Criteria 3 - Public Facilities Designation Changes: This category corrects the LUDs for privately owned lands erroneously designated as "Public Facilities" (PF), which normally designates lands slated for public benefit uses. It affects a total of roughly 190 acres of Riverside County. In most of the cases, the proposed new LUDs would have virtually no effect (adding only a handful of homes, for example). Two sites have growth-inducing changes that would lead to upwards of 50 homes and nearly 300 homes. Another site would accommodate up to 20 acres of Light Industrial development. For these three locations, however, analysis of the parcels involved relative to their regional surroundings and, in particular, their Area Plans indicate that their resultant development potential increases would be small. Further, none of these parcels represent significant encroachments into remote or isolated areas. As a result, these changes would not result in significant growth inducement. Thus, the changes proposed under Criteria 3 were collectively found to not be significantly growth inducing within Riverside County.

Criteria 4 - Open Space-Conservation Designation Changes: This category addresses lands that were originally designated as "Open Space-Conservation" (OS-C), but have been determined to be unsuitable for such due to existing development, location or other constraints. This category affects a total of 28 acres of Riverside County. In most of the cases, the proposed new LUDs would have virtually no effect (adding less than a dozen homes, for example). For this reason, the changes proposed under Criteria 4 would not result in significant inducement of growth.

Criteria 5 - Open Space-Recreation Designation Changes: This category addresses a single 38-acre area inappropriately designated as "Open Space-Recreation" (OS-R). It would be designated as Medium-Density Residential (MDR) under GPA No. 960. This change would be inherently growth-inducing, as it would accommodate roughly 75 to 190 dwelling units on the site. Its location, however, on the eastern side of the Coachella Valley, is on lands clearly urbanizing to similar uses. When compared to the overall development expected within the Western Coachella Valley Area Plan in which it is located, the growth inducement is found not to be significant.

Criteria 6 - Appropriate Designation for Public Use Lands: Under this category, roughly 800 acres of public lands erroneously designated for private development uses, instead of Public Facilities (PF), would be corrected. These changes include, in particular, PF designations applied to lands buffering landfills, Riverside County facilities (e.g., the Hub Jail), reservoirs (e.g., Lake Skinner), canals and major roads. Item C6-4, in particular, alters LUDs to accommodate the revised 100-year floodplain resulting from changes made to the Prado Basin and its dams. As such, the Criteria 6 changes generally denote new limits on development, rather than new growth potential. For this reason, the changes proposed under Criteria 6 would not result in significant inducement of growth.

Criteria 7 - Designations Appropriate for Existing Lot Sizes: This category proposed LUD changes to roughly 11 acres to accommodate estate-density residential uses in an area surrounded by similar existing development. As such, it represents an orderly extension of existing development. And, though technically an inducement of growth, compared to the existing AG designation, it would only increase the number of homes in the Southwest Area Plan by roughly five units. As such, this minute change does not represent a source of significant growth inducement in the area.

Criteria 8 - Other Land Use Changes: This category addresses various LUD changes identified over time that do not fit into any of the other categories above. Four areas would be moved from residential to commercial or industrial uses and three would be changed in the reverse. In total, 250,000 square feet of additional commercial

and industrial uses would be added. Likewise, three areas would be re-assigned to residential LUDs with lower densities (totaling 710 acres with 340 potential dwelling units – a decrease of over 750 units) and five areas would go to LUDs of increased residential densities (a total of 1,105 acres accommodating an additional 162 dwelling units). The LUD changes increasing housing development potential or business use intensities would inherently increase growth potential. However, analysis of the overall effect of the changes proposed under Criteria 8 with respect to the affected Area Plans in which they are located, found that these changes would not be significantly growth inducing. Three of the proposed changes would have the potential to induce growth, but not at significant levels (0.2% to roughly 2%).

13. Fish Farms

This project component represents roughly 860 acres where the existing LUD would be changed to agriculture (AG) to reflect existing or planned aquaculture (fish farming) and related activities. Though agricultural uses would foster economic growth and jobs, the low levels of development associated with such activities would severely limit their growth potential. Further, some of the acreage to be shifted to AG was previously designated for residential uses. As such, the change would represent the loss of additional future housing development. Lastly, however, the proposed changes were evaluated at the regional level against the build out potential for the Eastern Coachella Valley Area Plan in which they are located. It was found that the proposed changes would affect less than 1% of the area and have only a small effect on the area's growth. For these reasons, these proposed project components were not found to be significantly growth inducing.

14. General Plan Circulation Network Changes

As part of the overall General Plan update process, the County Transportation Department examined the existing Countywide Planned Circulation System to determine if regional and local transportation systems would be able to accommodate the traffic demands of the planned future intensities resulting upon General Plan build out, as well as those associated with GPA No. 960. As a result, GPA No. 960 includes a number of updates to proposed roadway alignments and intersection locations, as well as functional classifications (widths, number of lanes, level of service targets, etc.), where needed throughout unincorporated Riverside County.

Because of the essential nature of vehicular access to and across sites, the introduction of new roadways is quintessentially growth inducing. By facilitating access, new roads foster economic and population growth, open up areas for construction of additional housing, particularly in isolated or remote regions, and remove an impediment to growth by establishing an essential public facility. Often individual private development projects propose roads specifically to serve the proposed land uses. However, in the case of GPA No. 960, a number of roadway changes are being proposed of varying types and for locations across Riverside County. As such, they represent the further extension of roadways necessary to the serve the growing county and are considered collectively growth producing. Thus, because of the extent and essential nature of the proposed revisions to the Riverside County Circulation Network, these GPA No. 960 changes would be considered to be significantly growth inducing.

15. Traffic Level of Service (LOS) Standard Changes

As shown in Table 4.18-B in Section 4.18 (Transportation and Circulation), the County Transportation Department proposes adjustments to the volume capacities for certain types of roadways, mainly arterial and larger. The proposed level of service (LOS) changes do not in any way alter the *amount* of traffic *generated* that would be carried by affected roadways, as traffic is primarily a function of population (travelers) and geography

(that is, the destinations or "trip ends" determined by the locations of various land uses). However, the changed standards mean that in some cases roadway improvements (i.e., expanding the capacity of existing roadways and/or adding new roadways or capacity) would not be triggered until higher traffic volumes are reached. The exception is "Mountain Arterial," which would have a lowered LOS and thus trigger improvements sooner than present standards). While future projects would still be required to pay into the TUMF program for mitigating regional traffic impacts, the requirement for project-specific roadway improvements would be somewhat eased. This change (that is, delaying the triggering of roadway, signal and related infrastructure improvements) could ultimately have the effect of the removal of a barrier to growth by decreasing the time and expense of transportation-related improvements associated with implementing a proposed project. As a benefit, by removing this obstacle to growth, this change could result in the indirect fostering of economic growth, population growth and indirectly in the construction of additional housing. In terms of environmental impacts, however, this component of the project would be significantly growth inducing.

16. Non-Motorized Transportation Plan Changes

Within the Circulation Element, GPA No. 960 also includes updates to both the alignments proposed for the Riverside County Non-Motorized Transportation Plan, as mapped in Figure C-7 of the General Plan (as well as detailed in the individual Area Plans), and to the standards for trail alignments, types, usage and functional classifications, and related implementation policies. However, because trails generally serve to provide either pedestrian connectivity and/or recreational opportunities, they are not inherently growth inducing. Rather, they most often tend to be developed in response to an area's growth, rather than a driver of such growth. For these reasons, the proposed changes to the Riverside County Non-Motorized Transportation Plan and other trails-related policies would not result in significant inducement of growth.

17. Multipurpose Open Space Element Changes

The Multipurpose Open Space Element was examined to ensure that countywide policies addressing natural resources (their regulation, use and conservation) remain appropriate and adequate for current conditions and the planned future of Riverside County. Thus, GPA No. 960 includes a variety of new and revised policies to strengthen resource protection, energy conservation and infrastructure coordination. A variety of resource maps were also updated addressing the distribution of known resources to better coordinate their conservation and protection, where appropriate. Review of the specific policies and map revisions proposed found none of them met any of the qualitative or quantitative criteria for growth inducement outlined earlier in this section. Thus, the changes proposed to this Element under GPA No. 960 would not result in any significant inducement of growth within Riverside County.

18. Safety Element Changes

Similarly, the General Plan's Safety Element was also examined to ensure that countywide policies addressing safety hazards, risks and preparedness remain appropriate and adequate for current conditions and the planned future of Riverside County. Thus, GPA No. 960 proposes several new and revised policies to reduce hazards and improve safety, such as for updated geological, seismic and fire-hazard planning. The accompanying maps were similarly updated to reflect current information. In all, a number of safety maps were updated addressing various safety hazards and zones to better coordinate the protection of people and property within Riverside County. These items address safety hazards and protection, and establish limits on growth (due to the mapped hazards) to ensure public safety. Review of the specific policies and map revisions proposed found that none met any of the qualitative or quantitative criteria for growth inducement outlined earlier in this section. Thus, the changes

proposed to this Element under GPA No. 960 would not result in any significant inducement of growth within Riverside County.

19. Air Quality Element Changes

The Air Quality Element was also updated under GPA No. 960. Changes proposed address regulatory updates and the provision of new information. In particular, additions are proposed to address recent California laws and policies related to greenhouse gas (GHG) emission reduction, including GHG reduction targets based on a countywide carbon inventory, as well as goals and policies were developed to achieve these reduction targets in coordination with the Climate Action Plan (CAP) that has also been developed for Riverside County. The CAP includes a program for enacting Implementation Measures to be used to ensure that future development within unincorporated Riverside County achieves Riverside County's greenhouse gas reduction goals. These actions ensure the County of Riverside is consistent with the State of California's overall GHG reduction plans developed to implement AB 32, California's Global Warming Solutions Act of 2006. See Section 4.7 of this EIR for more information.

Because of the need to prevent future GHG emissions, the proposed changes include a number of items directed at reducing emissions (of both GHGs and, incidentally, criteria pollutants) associated with new development. That is, they assume future development will occur and propose ways to mitigate the effects of said new development on air quality and GHGs accordingly. In essence, this means they react to future development proposals rather than inducing or promoting them directly. For this reason, the GPA No. 960 changes proposed for the General Plan's Air Quality Element would not serve to significantly induce growth. For the same reasons, the proposed Riverside County Climate Action Plan would likewise not induce significant growth within Riverside County.

20. Administration Element Changes

The proposed update to the Administration Element of the General Plan was examined and updates are included in GPA No. 960 where needed to ensure its policies and programs continue to reflect current planning practices and provide a clear and concise set of directions for the implementation of the General Plan. Because of the administrative nature of these proposed changes, they tend to either have no effect on growth. In the case of the proposed change to allow more frequent processing of lands *into* the OS-C designation where flood control issues arise, the change would impede future growth, rather than foster it. Thus, collectively, none of the changes proposed to this Element under GPA No. 960 would serve to induce significant growth within Riverside County.

21. Updates to General Plan Appendices

Several of the technical appendices to the General Plan were updated, revised or reissued as necessary to ensure that the General Plan continues to reflect current conditions and growth forecasts for Riverside County. These appendices were developed as part of GPA No. 960 to ensure up-to-date data is provided to support the policy and program directives in the General Plan and to update planning, land use, socioeconomic, potential environmental constraints (such as ambient noise or air quality levels) and other projections and analyses. As such, these appendices merely represent informational items used to inform or elaborate upon the rest of the General Plan. Thus, none of the proposed appendix changes would have the potential to induce growth within Riverside County.

D. Conclusions on Growth Inducement

Based on the above analysis, many of the proposed changes associated with GPA No. 960 would either limit or impede growth (for example, by placing further restrictions on floodplains or wildfire hazard areas) or would induce insignificant amounts of growth (less than 0.1% of the overall growth by Area Plan). The provision of small, scattered incidental rural-commercial retail uses in under-served regions that is expected to result from the proposed incidental rural-commercial policy proposal is an example of this kind of limited, insignificant growth. Only several key specific types of future development actions or projects resulting from GPA No. 960 would, in fact, have the potential to induce significant growth within Riverside County.

As analyzed above, these include three proposals that would foster economic, population and housing growth within a portion of Riverside County: the proposed Meadowbrook and Good Hope Rural Village Land Use Overlays, and the proposed Northeast Business Park Overlay. Changes to sites in the Criteria 2 LUD category would also result in significant growth-inducing effects due to their encroachment into remote or isolated areas. In addition, the proposed changes to the countywide circulation network also have the potential to induce significant growth because of the essential nature of roads in providing access to remote or isolated regions, and in removing impediments to growth by establishing an essential public facility. And, lastly, the proposed circulation LOS changes would be directly and indirectly significantly growth-inducing due to the removal of barriers to growth resulting from decreased the time and expense of transportation-related improvements associated with implementing a proposed project.

This finding of significant growth-inducing effects associated with GPA No. 960 is not unexpected, however, given the programmatic nature of the project, its countywide scope and the nearly 50-year build out period involved. The nature and purpose of a General Plan is inherently growth inducing, in that it represents a plan for ensuring the orderly growth and development of land within unincorporated Riverside County over time. As such, the myriad policies, plans, procedures and standards outlined throughout the Riverside County General Plan, as updated pursuant to GPA No. 960, as well as this EIR and the existing EIR No. 441, certified for the 2003 RCIP General Plan, collectively serve to mitigate and reduce, where possible, the severity of the environmental effects associated with growth and build out of Riverside County. With continued diligence in implementing the General Plan, long-term growth within the County of Riverside can continue while environmental effects are kept to the minimum feasible and the unique biological and other important natural resources of Riverside County are protected for the health and enjoyment of both existing residents and future generations to come.

Section 5.5 Cumulative Impacts

A. Introduction

Section 15130 of the State CEQA Guidelines requires that an EIR include a discussion of the potential cumulative impacts of a proposed project. Cumulative impacts can result from individually minor, but collectively significant, impacts occurring over a period of time. Specifically, cumulative impacts are defined as two or more individual effects that, when considered together, are substantial or that compound or increase other environmental impacts. The cumulative impact from several projects is the change in the environment that results from the incremental impact of development when added to other closely related past, present and reasonably foreseeable or probable future developments. The State CEQA Guidelines, CCR Section 15130(b)(1), outlines two ways in which analysis of a project's cumulative impacts may be approached:

The following elements are necessary to an adequate discussion of significant cumulative impacts. Either:

(A) [List Method]: A list of past, present and probable future projects producing related or cumulative impacts, including, if necessary, those projects outside the control of the agency, or

(B) [Regional Growth Projections Method]: A summary of projections contained in an adopted local, regional or statewide plan, or related planning document, that describes or evaluates conditions contributing to the cumulative effect. Such plans may include: a general plan, regional transportation plan or plans for the reduction of greenhouse gas emissions. A summary of projections may also be contained in an adopted or certified prior environmental document for such a plan. Such projections may be supplemented with additional information such as a regional modeling program. Any such planning document shall be referenced and made available to the public at a location specified by the lead agency.

Thus, to quantify future development trends for the Riverside County General Plan, current General Plan Amendment (GPA) applications in process with the Riverside County Planning Department were used to represent reasonably foreseeable future projects. In general, GPA cases are often broad enough to capture large planning projects in unincorporated Riverside County, including large specific plans, but narrow enough to allow for cumulative analysis. Also, since all of the GPAs submitted to the County of Riverside must use the same basic land use assumptions (i.e., those of the current General Plan), the GPAs can be quantified and combined in a manner that permits appropriate comparisons. To study the relative cumulative effects of the project, GPA No. 960, in relation to various General Plan build out scenarios, a data set was created of all proposed GPA applications submitted to Riverside County since the issuance of the last collective General Plan in 2003, a total of ~~roughly 140~~ *126* ~~cases, which are described in more detail below~~. *(Of the GPAs included on the list, 18 were omitted due to various actions that had rendered them not applicable, e.g., cases that had been denied by the County, withdrawn or abandoned by the project applicant or vacated by judicial action. A handful of GPAs with no spatial component, e.g., changes to text, such as policy language, only were also omitted since they had no material effect on existing or proposed Land Use Designations or other analyzable spatial elements.)*

The resultant data set was used to assess the reasonably foreseeable future cumulative effects expected to occur within Riverside County as the General Plan guides development over time. These include spatial (land-based) impacts, in which environmental impacts are site-dependent (i.e., based on the resources present at a given location) and socioeconomic effects that arise from demand on resources caused by an increase in population, homes, jobs or other factors. The theoretical (hypothetical) demographic data (jobs, population and housing) used here were derived from the land use capacities indicated by the General Plan land use designations (LUDs) proposed for the various GPAs. Regional data developed by the Southern California Association of Governments (SCAG), which encompasses Riverside County in addition to five other surrounding counties, as well as the hundreds of cities within these counties, was also used to examine effects outside Riverside County boundaries. This particularly applies to population-driven regional impacts that extend beyond Riverside County, traffic in particular.

B. Cumulative Analysis – Methods and Results

To study the cumulative impacts expected for GPA No. 960, a data set was created of all proposed GPA applications submitted to Riverside County since the issuance of the last collective General Plan (i.e., the RCIP General Plan document, which was adopted by the County Board of Supervisors on October 3, 2003) through the end of 2009. In total, this amounted to *115* ~~138~~ GPAs~~, which are described in more detail below~~. This total also includes *11* ~~16~~ GPAs that were approved in 2009 after the initial baseline was set for this EIR, as they had not been incorporated into the "Existing General Plan" document, which only includes GPAs adopted through

the end of 2008. The cases included in this cumulative data set ("CULM" herein) are listed in Table 5.5-A (General Plan Amendments Included in Cumulative Build Out Scenario). See Appendix EIR-*11* ~~10~~ for additional details on the individual GPA cases that contribute.

The resultant cumulative data set, with GPA No. 960 added, was compared to a base plan consisting of the current (*2009* ~~2008~~) General Plan as well as to the existing conditions within Riverside County. By listing all of the GPAs currently in process as the "probable future projects" for cumulative impact analysis, that is, using the "List Method" mentioned above, the incremental contribution of the proposed project, GPA No. 960, *can* ~~could~~ be examined. In certain cases, in order to quantify and compare cumulative project impacts, the "Regional Growth Projections Method" was used instead, for example, for traffic and circulation impacts.

For the cumulative analysis presented here, it should be noted that this EIR does not evaluate the site-specific impacts of the individual GPAs listed. The *104* ~~122~~ GPA applications (i.e., those not yet approved or denied by the Riverside County Board of Supervisors; the other *11* ~~16~~ GPAs in the set are already adopted) must each undergo appropriate CEQA analysis and review in their own right, including any and all separate environmental studies deemed necessary on a case-by-case basis.

In addition, it should also be noted that growth in neighboring counties and cities as a result of build out of the overall cumulative scenario would likely cause secondary cumulative impacts in the County of Riverside. This effect is discussed herein to the extent the proposed project, GPA No. 960, contributes to such impacts, but it is not studied in detail due to geographical and technical limitations. This problem arises because each individual city and county makes a separate set of assumptions, growth predictions and build out projections for their own individual general plans. The widely varying methods and time horizons for build out of these jurisdictions lead to highly subjective results that make an appropriate "apples-to-apples" comparison infeasible.

Table 5.5-A: General Plan Amendments Included in Cumulative Build Out Scenario

Footnotes:

1. The Administrative Element of the General Plan establishes the Certainty System with four "amendment categories" as listed in Footnote 2. See pages A-11 through A-13 of the General Plan for specifics on each. GPAs ~~marked with an asterisk ("*") are those GPAs~~ adopted as of the end of 2009 *are not included on this list because they were instead included as part of the baseline General Plan ("CURRENT" scenario)*. GPA sub-cases (substantial conformances, etc.) *are also* not shown.
2. Key to types of General Plan Amendment (more than one category may apply):
   T = Technical Amendment F = Foundation Amendment
   EP = Entitlement/Policy Amendment AG = Agriculture Foundation Amendment
3. "SP" denotes GPAs associated with an existing or proposed Specific Plan. Pursuant to General Plan Policy LU 1.11, Certainty System rules apply slightly differently. SP-related GPAs are typically E/P types, but can also include any of the other three categories.
4. All "type" indicators listed above are descriptive, based on LUD changes appearing in the CULM data set and are listed here only to provide an approximate categorization of the GPA. They do not represent any official opinion, commitment or judgment on the part of the County of Riverside with respect to any individual GPAs or its merits. This list has no bearing on any existing or future processing or review of the individual GPAs.

Source: Riverside County Planning Department, data assembled *December 2014* ~~February 2013~~.

Therefore, rather than use the numerous disparate methods and factors of each jurisdiction, the analysis prepared by the Riverside County Center for Demographic Research (RCCDR), in consultation with the Riverside County Planning Department, applied a single set of uniform assumptions to all of the incorporated cities within Riverside County. The growth assumptions applied to the incorporated cities used regional data from SCAG. As discussed in Section 5.6 (Regional Consistency), SCAG is the regional planning entity responsible for working with the numerous cities, counties and other governmental agencies within Southern California to ensure sound, coordinated growth continues for the region. The end result of this effort was the development of a single, unified cumulative data set that enabled the examination of the project's incremental contribution to the various overall cumulative environmental impacts associated with growth in Riverside County.

1. Terms and Assumptions

For the cumulative analyses that follow, the following labeling conventions and assumptions apply:

- Existing, i.e., baseline, conditions within Riverside County are those present as of the date of this EIR's NOP or other date(s) as indicated in the applicable EIR section addressing the resource (i.e., Sections 4.2 through 4.19). These conditions are typically labeled "EXIST."

- The terms "existing General Plan" or "current General Plan" are used to refer to the current (2008) General Plan. *For this analysis, "current" means it incorporates all GPAs adopted through the end of 2009.* "CURR GP," "CURR scenario," etc., refer to the future build out of the current (*through 2009* ~~2008~~) General Plan.

- The term "updated General Plan" (or "GPU") is used to refer to the current (*2009* ~~2008~~) General Plan as it would exist updated pursuant to the proposed project, GPA No. 960, if adopted. Also abbreviated "GPU/960" since it encompasses the revisions proposed by the project.

- The final "cumulative data set" discussed throughout this section *typically encompasses both* ~~consists of a combination of~~ GPA No. 960 and the future GPAs. That is, it is the existing (*2009* ~~2008~~) General Plan with the changes proposed by GPA No. 960, as well as the *115* ~~122~~ individual GPAs included in the "future GPAs," *as well as* ~~plus~~ the *11* ~~16 additional~~ adopted GPAs. It is this overall cumulative General Plan that is referred to as the "cumulative scenario," *"CULM,"* "CULM build out," etc.

- When the proposed project, GPA No. 960, or "project build out" is mentioned, for the purposes of this section only, it is assumed to referred to the build out of the existing (*2009* ~~2008~~) General Plan as

amended pursuant to GPA No. 960. Thus, the labels "GPU," "GPU960" or "GPA 960 scenario" refer to the entire General Plan, not merely the individual components of the plan that are proposed for change under GPA No. 960. ~~Again, it should be noted~~ *Note* that this distinction applies only in Section 5.5.

- Each of the General Plan scenarios assume full (100%) build out of the land uses mapped, even if such development would be historically or economically unlikely or otherwise constrained from ever actually occurring *(for example, due to MSHCP conservation requirements, earthquake fault setback requirements, etc.)*. This is done to ensure the "worst case" is analyzed and appropriate mitigation identified where needed.

- The environmental analyses that follow include conclusions as to the potential for cumulative impacts for the project, GPA No. 960, and also for the CULM scenario. Although oft-times included in the cumulative effects presented, results for the existing (CURR) General Plan are generally not specifically addressed since they were already covered by EIR No. 441.

- A "build out scenario" denotes the level of development that would exist should all potential development be realized as planned for in the applicable document (General Plan, GPA proposal, policy area, etc.) indicated. The assumptions used in modeling each of the build out scenarios used herein are generally as directed in General Plan Appendix E-1, unless noted otherwise. See Section 4.1 for additional details on build out modeling.

The collection of "future GPAs" referenced in this section refer to the *115* ~~122~~ property owner-initiated GPA applications submitted through *the end of* 2009 and in process *(or approved)* with the County of Riverside Planning Department. The only GPAs from this timeframe not included in the data set are those that have been denied by the hearing body, formally withdrawn*,* ~~or~~ abandoned by the applicant *or vacated by judicial decision* ~~are the only GPAs omitted~~. GPAs that were "declined to initiate" during GPIP (General Plan Initiation Process) review were also omitted. Inactive (but not formally abandoned) GPAs *are still* ~~were~~ included in the *CULM* data*set* since they could in theory be reactivated at any time. The "future GPAs" data set includes *67* ~~63~~ active property-owner initiated GPAs submitted within the open "window" for requesting General Plan Foundation changes. (This "window" was opened for the first time in January-February of 2008 after a five-year interval pursuant to the General Plan's Administration Element policies.) Foundation GPA applications denied GPIP "initiation" (i.e., "declined to initiate") by the Board of Supervisors or withdrawn by the applicant were omitted.

Lastly, it should be noted that, notwithstanding the analysis of this section, all of the proposed GPAs in the CULM data set will still have to be processed as individual cases and are *not* included in the scope of this proposed project, GPA No. 960. None of the information or discussion in this EIR is specifically intended as CEQA analysis for these individual GPAs, though future analysis may use this EIR for tiering as allowed by CEQA. Each case will still require individual project-specific CEQA analysis and will be considered separately for approval or denial by the appropriate decision-making body. Inclusion on this list does not imply County endorsement in any way.

The CULM data set was created through the collaboration of three Riverside County departments: Planning, Transportation and GIS *(RCIT)*, as well as the Riverside County Center for Demographic Research (RCCDR). Planning staff collaboratively assembled a database of ~~each of~~ every open GPA application submitted to the County of Riverside. These were sorted to limit the list to applications received through the end of 2009 to correspond to the cut-off point for the EIR. As noted above, this resulted in a total list of *115* ~~138~~ GPAs. *Another 15* ~~The 16~~ GPAs *that were* adopted between the date of the *original 2008* "current" ~~(2008)~~ General Plan and the end-of-2009 EIR cut-off point were ~~also~~ included*, but as part of the CURRENT scenario, rather than the CULM scenario* ~~in the list to ensure consistency amongst the various analyses both within this section and throughout the rest of the EIR's chapters. See Appendix EIR 11 for more details~~.

The data developed for the cumulative data set are based only on "worst-case" scenario build out of all available land uses. This was done to ensure that this EIR analyzes the full spectrum of development/ land use *capacity* identified by the various General Plan scenarios discussed in this section. In reality, the *actual* future demographics of Riverside County (and, hence land use build out) are influenced greatly by a number of subtle and varied demographic, economic and political factors. For example, Riverside County's official demographic forecasts are much more complicated and sophisticated projections than those used in this section. However, adjusting each of the scenarios (including each of the *115* ~~138~~ GPAs) for such myriad details and factors was infeasible within the scope of this cumulative impacts analysis.

For each of the cumulative impacts analyzed herein, the CULM data set was compared against existing conditions (baseline data set*, which represents the current state of development in the county*) and the two other General Plan build out scenarios mentioned above: the existing (*2009* ~~2008~~) General Plan (CURR GP) and the General Plan as it would be if amended by GPA No. 960 (i.e., the GPU build out scenario). For further details on how the spatial analyses were conducted for each of these scenarios, see Subsection 5.5.D.1 (Land Use), below.

2. Cumulative GPA Build Out Scenario - Data and Projections

The work efforts outlined above resulted in the creation of a CULM build out scenario data set that includes both a land use capacity (spatial) component and a set of demographic projections. The total acreages for each LUD associated with the CULM data set are shown in Table 5.5-B (Land Use Summary for Cumulative GPAs Build Out Scenario), below. The demographic results are shown in Table 5.5-C (Demographic Summary for Cumulative GPAs Build Out Scenario). Additional details on each of the data sets used in this section are provided in Appendix EIR-11.

Footnotes:
1. CD = Community Development Foundation; RC = Rural Community Foundation; RUR = Rural Foundation; OS = Open Space Foundation. Foundation is CD if not listed otherwise. For LUD abbreviations, see Table 4.2-D.
2. Change in acreage (+/-) attributed to the CULM GPAs data set. (TOT-CULM Δ scenario in Appendix EIR-11.)
3. TOT-CULM scenario build out = build out of Current (*2009* ~~2008~~) General Plan as amended per CULM GPA data set plus GPA No. 960 changes. See Table 5.5-A for list of GPAs encompassed by CULM GPAs DATA SET. (Labeled "TOT-CULM" in Appendix EIR-11 tables.)
4. TOT-CULM SCENARIO BUILD OUT minus EXISTING (baseline existing uses of land). (ENVI-TOTCULM Δ scenario in Appendix EIR-11.)
5. MUPA = Mixed Use Planning Area; CC = Community Center.
6. Not an LUD in the General Plan; category used for existing uses of land and/or GIS mapping only.
7. Existing "Natural Open Space" and undeveloped public/quasi-public parklands categorized as "OS-C." Existing "Natural (Reserve)" categorized as "OS-CH." Existing land uses under OS-W include "Water (Colorado River)."
8. For built uses, LUDs generally include roadway acreages (i.e., those totals not included in "roadways").

Footnotes:

1. CURRENT GP = Current (*2009* ~~2008~~) General Plan; OVERALL CULM BUILD OUT = the current (*2009* ~~2008~~) General Plan, plus the GPA No. 960 changes, as well as the changes proposed by the existing GPAs approved or applied for through the end of 2009 (see Table 5.5-A). Also see Table 5.5.B footnotes for additional land use notes.
2. Change in acreage (+/-) attributed to the CULM GPAs data set. ("CULM Δ" scenario in Appendix EIR-11.)
3. TOT-CULM SCENARIO BUILD OUT = Build out of Current (*2009* ~~2008~~) General Plan as amended per CULM GPA data set plus GPA No. 960 changes. See Table 5.5-A for list of GPAs encompassed by CULM GPAs DATA SET. ("TOT-CULM" scenario in Appendix EIR-11.)
4. Residential Uses encompass: Urban/Suburban: LDR, MDR, MHDR, HDR, VHDR and HHDR (all CD Foundation); Rural/Agricultural: EDR, RC-EDR, VLDR, RC-VLDR and RC-LDR; Interface/Wildland: RR, RD, RM and OS-RUR. ("ENVI-TOTCULM Δ" scenario in Appendix EIR-11.)
5. Commercial & Industrial Uses encompass: CR, CT, CO, LI, HI, BP, CC and MUPA.
6. Public Facilities & Infrastructure Uses encompass: PF, FWY and MISC. (FWY and MISC are not LUDs, rather they denote existing uses of land and/or GIS mapping categories only.)
7. Natural Resource Uses encompass: Rural/Agricultural: AG and OS-MIN; Interface/Wildland: OS-REC.
8. Open Space encompasses: OS-C, OS-CH, OS-W and VAC (VAC is an existing use of land designation, not a General Plan LUD).

Source: SCAG, 2008. County Center for Demographic Research, 2010. Riverside County Planning Dept., Project application materials, 2013.

3. Environmental Assumptions

The specific methods used for modeling environmental effects are as outlined in the corresponding parts of Section 4.0. The modeling in the cumulative effects subsections uses *theoretical* projections because specific area-by-area calculations for each resource, using each independent area or agency's own variables and procedures (for

example, each of the 23 individual water districts or each school district) were beyond the scope of this programmatic analysis. In addition, controlling these variables in the modeling process by using standardized factors countywide enables valid comparisons amongst the various scenarios and regions for the given resource. Notwithstanding any of the modeling used herein, the ultimate methods and timing for meeting the resource needs discussed in this section will always be at the discretion of the responsible agency. For example, each individual school district determines where, when and what type of schools are built within its district, regardless of any land use designations in the Riverside County General Plan. This also applies to water agencies, park districts, municipalities, etc. Thus, the cumulative data herein should not be construed as the *actual* specific needs, demands or effects that would arise for a given location *(which are generally population, not capacity, based)*. Such determinations will be made on a project-by-project basis as development occurs and may vary based on the surrounding area.

The theoretical projections herein are also based on the assumption that all the land uses proposed under each scenario *will* develop fully and as mapped/planned. As such, each represents the theoretical, worst-case scenario and likely over-states the actual real-world development potential likely to result*, even though in real life, 100-percent build out of all areas throughout the County is highly unlikely based on historical development patterns*. Actual future development of individual parcels and areas mapped in the various build out scenarios, including those of GPA No. 960, are subject to the discretion of many hundreds to thousands of individual property owners, including private individuals, business entities and even various public agencies and other entities. The County of Riverside has little to no control over the decision to propose development (new or redeveloped) on a given site although the County of Riverside is the entity with discretion for review and approval of such development applications for most cases within unincorporated Riverside County. Demand for additional development is often a result of many interrelated factors, including population growth and economic demand, as well as location, local supply, infrastructure availability, costs, etc.

C. Cumulative Effects

In this subsection, each of the individual areas of environmental analysis previously covered in Section 4.0 (i.e., Sections 4.1 through 4.19) are addressed here for the CULM scenario and the project's incremental contributions to the cumulative effects of Riverside County build out. According to the State CEQA Guidelines, CCR Section 15130 (b):

> *"The discussion of cumulative impacts shall reflect the severity of the impacts and their likelihood of occurrence, but the discussion need not provide as great detail as is provided for the effects attributable to the project alone. The discussion should be guided by the standards of practicality and reasonableness, and should focus on the cumulative impact to which the identified other projects contribute rather than the attributes of other project which do not contribute to the cumulative impact."*

Accordingly, in the subsections that follow, each environmental topic is described relative to its existing setting and future conditions, as they apply to the cumulative scenarios developed for this EIR. The existing setting, project-specific effects, impacts and mitigation for each environmental topic have already been provided in Sections 4.1 through 4.19. Thus, to avoid repetition, the discussions below refer back to those sections where ever possible. Also, see those sections for information on the specific sources and data development methods employed for each environmental resource or topic. The discussions below focus on the cumulative impacts that are significant and, in particular, those areas where the project's contribution to such cumulative impacts would be considerable. Lastly, *at the end of this subsection* ~~following these discussions is~~ a table summarizing the project's overall cumulatively substantial impacts *is presented*.

1. Cumulative Effects on Land Use

Section 4.2 (Land Use) of this EIR discusses in great detail the existing uses of land within Riverside County, as well as the land use data sources used. The section also analyzes the impacts that would arise from future development accommodated by the changes proposed by the project, GPA No. 960, as well as the regulatory mitigation measures that would ensure impacts are less than significant. Thus, to avoid repetition, information already covered in Section 4.2 is not repeated here. The reader is encouraged to refer back to Section 4.2 directly for additional details on land use.

a. Existing and Future Conditions

Within Riverside County are 26 incorporated cities, which are not included in the scope of the Riverside County General Plan other than for planning and coordination purposes. The General Plan and the proposed project's land use data were updated to reflect the transfer of the cities of Wildomar and Menifee from County land use jurisdiction. Two other new cities, Eastvale and Jurupa Valley, are included in *most of the analyses in* this EIR, as their incorporations occurred well after the April 13, 2009, release of the NOP for this project. This means that impacts to northwestern Riverside County are addressed by this programmatic EIR, even though they now represent impacts to cities (and hence are not subject to County of Riverside jurisdiction). *Since they were prepared later, the cumulative analyses in this section do, however, exclude from all scenarios any proposed GPAs that fall into lands now part of any incorporated city.*

Existing development and uses of land within Riverside County are a mosaic of varying types of uses, ownerships, character and intensity. Table 5.5-D (Cumulative Land Use Effects) shows the generalized existing (*as of* 2008) land use throughout Riverside County based on raw data provided by SCAG and developed by RCCDR. This table defines land uses into *five* ~~four~~ broad categories (Urban/Suburban, Rural/Agricultural, Interface/Wildland*, Public Facilities* and Vacant/Open Space) based on the associated level of development density and intensity.

The table also shows three scenarios for General Plan build out which were developed from the three land use scenarios described in the introduction to this section: build out of the current (*2009* ~~2008~~) General Plan ("CURR GP"), the updated General Plan as amended per GPA No. 960 ("GPU") and the General Plan as amended per the cumulative GPA set ("CULM" or "CULM GP"). These four land use build out scenarios were analyzed against various GIS data *maintained by the County of Riverside* ~~in RCLIS~~.

As shown in the table below, at present the majority of land within unincorporated Riverside County (just over 90%) is not developed. In particular, vacant and open lands *dominate* ~~predominant in~~ the eastern desert areas outside the Coachella Valley. Of the existing types of residential uses within the unincorporated county, 61% are of the rural or interface/wildland type and only 38% are within areas considered urban or suburban (e.g., lots under a half-acre). Of the developed areas, most are located in western Riverside County (i.e., roughly the third of the county located west of the San Jacinto Mountains) and the Coachella Valley. Large tracts of federal lands, including National Forests, account for open space areas in southern Riverside County, much of the San Jacinto Mountains and parts of the eastern desert as well. See Section 4.2 for additional details on the land use patterns existing within Riverside County and its cities.

In regards to land use-related cumulative impacts, Table 5.5-D reveals a number of trends *expected* as Riverside County develops over time. *These trends can be seen graphically in Figures 5.5-A and 5.5-B, below.* First, in the long run Riverside County will still be facing large growth pressures. Even with the slower pace of growth following the collapse of the housing market in the late 2000s, a substantial increase in growth is still anticipated to result in the implementation of future GPAs over the next 50 years if all of the changes proposed by GPA No. 960 and the cumulative General Plan scenario occur. *The slow-but-steady ongoing economic recovery shows growth continuing within*

Southern California, including Riverside County. These changes and growth pressures will have a direct bearing on land uses within Riverside County.

In terms of urban/suburban residential development, build out of the existing General Plan (CURR GP) will increase the amount of land devoted to residential uses by more than double (120%). In particular, nearly 50,000 additional acres of Medium Density Residential (MDR) are planned, which alone would accommodate nearly 180,000 additional homes. In Riverside County, this substantial increase will occur mainly through the development of vacant lands, with infill providing opportunities for densification and urbanization as communities mature. These effects were originally addressed by the EIR for the current General Plan (EIR No. 441).

The proposed project, GPA No. 960, would increase the amount of urban/suburban residential units planned by roughly 2,600 acres. *(See Table 1.6 in Appendix EIR-11.)* Incrementally, this contribution is not substantial, as it represents only 2% of the total urban/suburban residential area planned. Similarly, the cumulative General Plan scenario (CULM GP) would further add *2,150*~~2,300~~ acres to the urban/suburban residential total. *(See Table 1.7 in Appendix EIR-11.)* Proportionally, this increase is also only a 2% increment and also not substantial.

Given the nature of Riverside County, the vast majority of land planned for residential development (e.g., per the current General Plan) is located in rural areas. Specifically, the existing General Plan *(CURR)* calls for *nearly 2.24* ~~over 2.32~~ million acres of rural residential uses, particularly in the Interface/Wildlands category (i.e., lots 5 acres and larger). This is a substantial increase addressed under EIR No. 441. It should be noted, however, that this increase represents all of the lands designated for rural residential land uses within Riverside County, including vast portions of the far eastern desert (beyond the Coachella Valley) that are designated OS-RUR (open space-rural) by default. The OS-RUR designation is frequently used in the remote and least-developed portions of Riverside County to provide the minimal level of development potential necessary for private lands. It is unlikely that all of the lands so-designated would actually see development based on historic and economic data and trends. However, this EIR and this cumulative analysis nevertheless assume full development in order to ensure a "worst case" scenario.

With its reduced or eliminated footprints for several rural villages and other rural areas, GPA No. 960 would lessen the severity of land use effects by reducing the amount of residential acreage planned in outlying rural areas (i.e., wildlands and interface). In total, the project *(GPU scenario)* calls for *13,300 fewer* ~~over 12,400~~ acres *of* ~~less~~ rural residential uses. *(See Table 1.6 in Appendix EIR-11.)* Similarly, the cumulative General Plan scenario would further reduce interface/wildland residential uses by *nearly 17,000* ~~an~~ additional ~~16,720~~ acres. Even after accounting for the *nearly 7,000* ~~7,570~~-acre increase in the rural/agricultural category, this still yields an overall net decrease of *roughly 10,000* ~~9,150~~ acres for net non-urban residential. Thus, in total, either of these General Plan scenarios would have a net beneficial cumulative effect by slightly offsetting the existing General Plan's proposed increases in rural and interface residential acreage.

The need to extend infrastructure further into rural portions of Riverside County, particularly remote areas not currently served, however, would trigger additional environmental impacts associated with their construction and operation. For details on environmental effects associated with specific types of infrastructure see the relevant parts of Section 4.0: Section 4.10 for energy resources (including electricity and natural gas), Section 4.18 for roads and other circulation infrastructure, Section 4.17 for public facilities and Section 4.19 for water resources, including potable water, sewer and storm drainage. No new highways or major infrastructure that would divide a community (e.g., dams, canals or rail lines) are planned or proposed under GPA No. 960 or the cumulative General Plan scenarios. Environmental impacts associated with new major county highways were addressed initially in EIR No. 441 for the current General Plan and additionally through CETAP (Community Environmental Transportation Accountability Process) also undertaken (along with the MSHCPs) as part of the overall Riverside County Integrated Plan (RCIP).

In terms of non-residential uses, existing land use patterns show large amounts of land devoted to commercial, industrial and public facility uses. This includes areas buffering landfills, surrounding reservoirs, canals, public airports and other facilities. Table 5.5-D indicates build out of the current General Plan would result in a reduction of developed commercial and industrial uses by a third. Rural lands devoted to large-scale public facilities

(e.g., landfills, jails, canals, schools, highways, etc.) would decrease slightly after taking into account excess lands left vacant by base closures and other changes in proposed public uses. Under GPA No. 960, the amount of commercial and industrial uses would increase slightly (by 430 acres), but the amount of public facilities would decrease by 570 acres. Thus, the project would contribute to a net benefit environmentally by reducing the potential public facilities footprint within Riverside County.

Under the cumulative General Plan scenario *(CULM)*, land devoted to public facilities would be further reduced by another 1,750 acres, a beneficial effect. Uses specifically proposed for Commercial-Retail (CR), however, would increase by *over* ~~nearly~~ 6,300 acres. In total, the cumulative scenario would result in an increase of *nearly 7,200* ~~7,300~~ acres of developed commercial and industrial uses. This is an increase of more than 25% and would be cumulatively substantial if the effects of such development are not mitigated. Individual future implementing projects would be required to mitigate significant adverse environmental impacts through compliance with the General Plan EIR (No. 441), this EIR (if applicable), the MSHCPs, the proposed Riverside County Climate Action Plan and other applicable environmental programs, as well as individual CEQA compliance.

In terms of agricultural uses, build out of the current General Plan would result in the loss of roughly 31,000 acres of existing agriculture (the largest single-category loss for a developed use). Both the project (GPA No. 960) and the cumulative General Plan scenario would add further to these losses by slightly increasing the amount of agricultural lands allowed to convert to developed non-agricultural uses. GPA No. 960 would decrease the amount of land designated agricultural ("AG" LUD) by 1,240 acres; the cumulative scenario would subtract another *2,900* ~~3,130~~ acres from this amount. Thus, each of these scenarios would contribute incrementally (0.6% and 1.6%, respectively), but not substantially, to the loss of agricultural land uses.

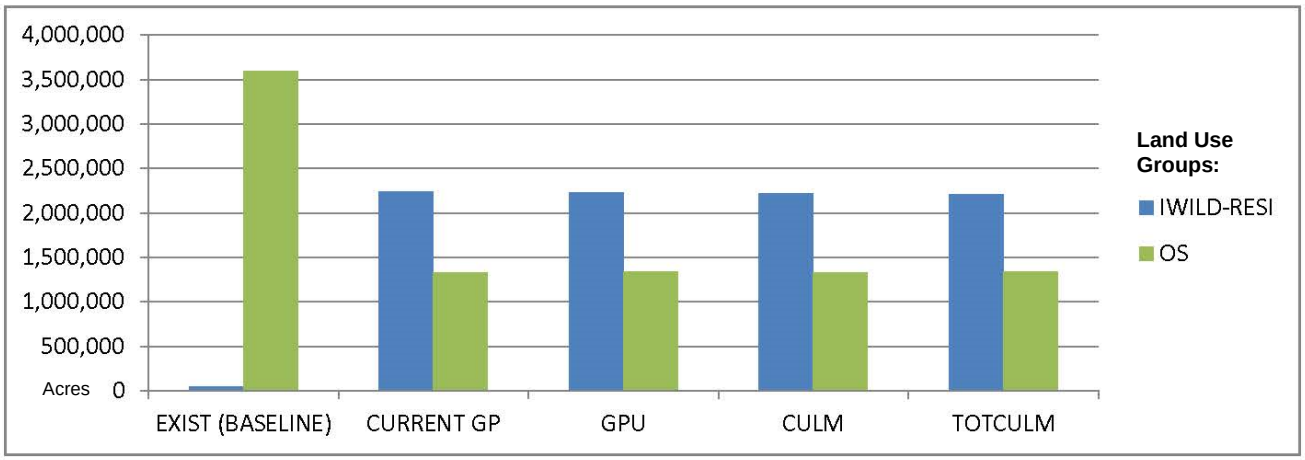
Lastly, the General Plan build out scenarios were analyzed relative to their effects on open space and vacant (undeveloped) lands. This issue was complicated by the difference between how SCAG classifies lands (i.e., as outlined for the Existing Uses of Land scenario in Table 5.5-B) and how the General Plan designates land uses. When developing a land use inventory, SCAG identified lands with no structures or other disturbances as "vacant." While descriptive, this term only reflects what is currently on a parcel, not what is *planned* for the land. Conversely, the land use mapping (LUDs) in the General Plan (and each of the build out scenarios analyzed here), do the exact opposite. They indicate what use(s) a parcel of land *may* someday develop, without regard for what is actually on the land at present. Also, they do not reflect the *likelihood* of the mapped use actually being realized, nor do they reflect when such development might occur. Accordingly, Table 5.5-D reflects this schism with existing lands labeled as "vacant." At build out, all unincorporated lands are assigned a specific use, even if that use is one that preserves the land in its vacant, undeveloped state, for example "OS-CH."

Despite these challenges, several trends were noted. *These trends can be seen in graphic form in Figure 5.5-C, below.* Under the current General Plan, vacant lands, including open space, would be reduced by over half (63%). EIR No. 441 found this loss of open space a significant impact, although the environmental effects of this loss are offset (though not reduced to less-than-significant) through a variety of means, including habitat conservation pursuant to the two MSHCPs covering parts of Riverside County. See Section 4.8 (Biological Resources) for specifics on this issue. The overall trend for the current General Plan is loss of "vacant" lands due to development of *roughly 2.2* ~~nearly 1.5~~ million acres of rural uses (particularly within interface and wildland areas). This is in addition to the offsetting effect of over preserving roughly 1.2 million acres as conservation lands (OS-CH, in particular) in the General Plan. (Note, the specific assembly of these OS-CH lands would be accomplished pursuant to the two MSHCPs; see Section 4.8 for specifics.)

Under GPA No. 960, the amount of land specifically preserved as open space (i.e., OS-C, OS-CH or OS-W) would further increase by *10,300* ~~nearly 11,500~~ acres, resulting in a net beneficial effect on the preservation of open space within Riverside County. The cumulative scenario would contribute *another* ~~nearly~~ 3,500 additional

acres as well. Thus, either scenario would contribute a net beneficial effect to the cumulatively adverse impacts associated with build out of the existing General Plan.

Figure 5.5-C: Wildland and Open Space Land Use Groups by General Plan Build Out Scenario



Footnotes:

1. *General Plan build out scenarios: EXIST = existing state of land development (as per SCAG aerial data), constitutes environmental baseline conditions; CURRENT GP = 2009 General Plan; GPU = Current (2009) General Plan as amended per proposed project, GPA No. 960; CULM = Current General Plan as amended per proposed GPAs used for this cumulative analysis; TOTCULM = General Plan build out with GPA No. 960 and all cumulative GPAs.*
2. *Land Use Group abbreviations: IWILD-RESI = Interface/Wildlands, all vacant/undeveloped, Rural Foundation and OS-Rural land uses. OS = All other vacant lands and open space land uses.*
3. *See Appendix EIR-11 for more information on these Land Use Groups and the aggregation methods used.*

b. Impacts

Future development accommodated by the project will contribute incrementally to cumulative land use impacts as Riverside County builds out (develops) over time pursuant to the Riverside County General Plan (regardless of scenario). Specific land use impacts of the severities indicated will include:

(1) Cumulatively Considerable Impacts

- Increase the number, density and intensity of residential and non-residential development within Riverside County, including both infill development and conversion of vacant land to developed uses.

- Increase the amount of roadways, storm drains, water reservoirs and storage tanks, pipelines, transmission lines and other infrastructure within Riverside County, including both as infill and through conversion of vacant land.

(2) Non-Substantial Incremental Impacts

- Physically divide an established community through development of intervening residential tracts, economic uses and, in particular, highways. (Though no new major highways or other circulation routes are planned in GPA No. 960. See the circulation discussion below for more details.)
- Conflict with land use plans, policies or regulations for avoiding or mitigating and environmental effect, in particular an Airport Land Use Plan (ALUP) or the proposed Climate Action Plan for reducing greenhouse gas emissions. (See the greenhouse gas and safety discussions, respectively, later in Section 5.5 for more on these.)
- Conflict with an HCP or MSHCP. (See biology discussion later in Section 5.5.)

c. Mitigation

As described in detail in Section 4.2.3, a variety of measures would be implemented to avoid, reduce and minimize adverse cumulative land use impacts. These include the following:

Key Regulations and Program: See Section 4.2.3 for details on each regulation.

- Federal Water Pollution Control Act of 1972 (Clean Water Act)
- Subdivision Map Act - California Government Code (CGC) section 66410, *et seq.*
- California Planning and Zoning Law - CGC sections 65000-66499.58
- State Aeronautics Acts - Public Utilities Code (PUC) section 21001 *et seq.*
- Ordinance No. 348 - Zoning and Land Use
- Ordinance No. 448 - Airport Approaches Zoning
- Ordinance No. 460 - Subdivision Regulations
- Ordinance No. 461 - Road Improvement Standards and Specifications
- Ordinance No. 509 - Agricultural Preserves
- Ordinance No. 576 - Regulating County Airports
- Ordinance No. 659 - Development Mitigation Fee for Residential Development
- Ordinance No. 671 - Consolidated Fees for Land Use and Related Functions
- Ordinance No. 673 - Establishing the Coachella Valley Transportation Uniform Mitigation Fee
- Ordinance No. 726 - Transportation Management Requirements for New Development
- Ordinance No. 748 - Traffic Signal Mitigation Program

- Ordinance No. 824 - Western Riverside County Transportation Uniform Mitigation Fee Program
- Ordinance No. 875 - Local Development Mitigation Fee for Funding the Preservation of Natural Ecosystems Under the Coachella Valley MSHCP
- Western Riverside County Multiple Species Habitat Conservation Plan (MSHCP)
- Coachella Valley MSHCP
- Riverside County Climate Action Plan (proposed in conjunction with GPA No. 960). See Section 4.7.3 for full details.

Key General Plan Policies: See Section 4.2.3 for the text of each policy.

- Land Use Element Policies: LU 1.1, 1.3, 1.5, 1.6, 1.8, 2.1, 3.1, 5.4, 7.6, 9.1, 9.4, 15.2, 15.3, 15.8, 19.1, 25.2, 28.6, 28.9, 30.3, 30.4, 30.6, 31.1-31.3 and 36.1
- Open Space Element Policies: OS 8.1, 17.1-17.3 and 18.1
- Circulation Element Policies: C 1.1, 1.2, 1.3, 1.4, 1.7, 3.7, 3.11, 3.12, 3.21, 3.30, 3.31, 4.1, 4.3, 4.6, 4.8, 4.9, 6.1-6.3, 7.1-7.4, 7.6, 7.8, 8.5, 8.7, 15.3, 15.4, 20.9 and 20.10

d. Significance

The analysis presented above indicates that future development consistent with the proposed project, GPA No. 960, would contribute less than significant incremental impacts on land use-related environmental issues, including physical division of an established community, consistency with land use plans, policies and regulations adopted to avoid or mitigate environmental effects, and consistency with habitat conservation plans. Moreover, implementation of, and compliance with, the above regulations, Riverside County ordinances and General Plan policies would ensure that cumulative impacts on land use are either avoided or minimized to less than significant.

2. Cumulative Effects on Population and Housing

Section 4.3 (Population and Housing) of this EIR discusses population and housing in detail, including future population growth and housing needs within Riverside County. It also analyzes impacts on population and housing from future development accommodated by the changes proposed by the project, GPA No. 960, and discusses individual project mitigation measures. Areas already covered in Section 4.3 are not repeated here.

The cumulative population, jobs and housing data presented in this subsection were developed pursuant to proposed General Plan Appendices E-1 and F-1. The land use-based data and associated build out projections are as outlined in Section 5.5.B. Data presented in Section 4.3 includes Table 4.3-A (Population Growth Trends, 1997-2007), Table 4.3-B (Housing Growth Trends, 1990-2007), Table 4.3-C (Housing Unit Building Permits Issued, 1990-2007), Table 4.3-D (Regional Housing Needs Assessment, 2006-2014), Table 4.3-E (Annual Average Payroll Employment by Industry, Riverside County 1999-2007), Table 4.3-F (Theoretical Build Out Projections (Land Use-Based Capacities) and Table 4.3-G (Comparison of Regional Projections).

a. Existing Conditions

Population growth in Riverside County as a whole has been quite rapid over the past two decades. As reported in proposed General Plan Appendix F-1, the population grew from approximately 1.2 million *in* 1990 to nearly 2.1 million as of January 1, 2008. In 2007, the unincorporated portion of Riverside County had a population of 537,600 people. Between 1997 and 2007, the population of unincorporated Riverside County increased by 26.7%.

Housing was the major driver of growth in Riverside County between 2000 and 2009. As indicated in Table 2 of proposed *General Plan* Appendix F-1, during this period Riverside County's housing stock grew by more than 34% (roughly 199,700 units). Average household size also increased steadily during that time, from 2.49 persons per household in 1990 to a peak of 3.09 persons per household in 2004. Since then, the average household size has declined slightly to 3.06 persons per household as of 2009. Since 2006, however, housing demand and home values have been greatly affected by changes in the national and local economies, as well as mortgage and banking industry changes. Housing starts have slowed markedly and this downturn has also affected employment in the region, as many construction jobs were lost.

b. Future Conditions

To provide a consistent set of projections across the various build out scenarios analyzed for cumulative impacts, the land use data (acreages) developed as outlined in subsection 5.5.B was used to model a series of *theoretical* socioeconomic data (SED) encompassing housing (dwelling units, du), population (based on the countywide standard of 3.06 persons per du) and jobs (based on the employment-generating factors associated with each economic land use). See Section 4.17 for specifics on the methodology used. The resultant SED data is presented in Table 5.5-E (Cumulative Socioeconomic Effects), below.

As Table 5.5-E shows, the overall residential density increases with each build out scenario as vacant lands infill. The urban *(USUB)* population would more than double by build out of the current General Plan; a cumulatively substantial increase. GPA No. 960 would incrementally add roughly 7% more people than already planned; a small fraction overall, but cumulatively substantial given the significance of the increase over existing conditions.

The development growth patterns are more noticeable within the rural/agriculture and interface/wildland areas of Riverside County. Demographic data indicate that as of *2009* ~~2008~~, roughly 15,600 homes occurred in these two categories on over 53,000 acres, housing nearly 42,000 people. Under the current General Plan, nearly *1,600,000* ~~2,300,000~~ additional acres of land would be subject to development potential, mainly in the form of Open Space-Rural Residential (OS-RUR), which allocates residential lots of 20 acres minimum. Based on historical trends and development patterns, it is unlikely that all of the OS-RUR lots within Riverside County would actually achieve full build out. Nevertheless, even if only 50% of the lots build out, the total area converted from vacant and open lands to rural residential would still be increasing 20-fold and the number of homes, particularly within the interface and wildland areas, would increase more than 10-fold. This increase would also result in a variety of related growth effects, such as the need for additional public services, energy resources (gas, electricity) and potable water. Under the GPU/GPA 960 scenario, 12,400 fewer acres of rural, interface and wildland development capacity would be allowed; resulting in over 11,000 dwelling units and over 33,000 fewer people being added to the region. The CULM scenario would decrease capacity by an additional *10,000* ~~3,200~~ acres, 8,000 homes and roughly 24,000 people.

Thus, overall build out of the current General Plan would increase residential units by *317,000* ~~250,000~~ and the number of people by *1.2 million* ~~765,000~~. The addition of the project's changes would add roughly 24,000 more homes and 72,000 more people (6% more). The addition of the cumulative build out scenario would add another 8% more people and homes on top of this (i.e., *10,500* ~~30,400~~ du and *33,000* ~~93,000~~ people). With the large

(176%) increase over existing conditions already associated with build out of the current General Plan, the incremental contributions of the proposed project and cumulative scenarios would be cumulatively significant. The extensive housing inventory that would result, however, would ensure that no people or homes are displaced by future development without replacement available.

Footnotes:

1. CURRENT GP = Current (*2009* ~~2008~~) General Plan; GP/GPA960 = the current (*2009* ~~2008~~) General Plan with the changes proposed under GPA No. 960 made to it; and, TOT CULM GP = the current (*2009* ~~2008~~) General Plan, plus the GPA No. 960 changes, as well as the changes proposed by the existing GPAs approved or applied for through the end of 2009 (see Table 5.5-A). Also see footnotes to Table 5.5.B for additional notes on land use descriptors.
2. Residential Uses encompass: Urban/Suburban: LDR, MDR, MHDR, HDR, VHDR and HHDR (all CD Foundation); Rural/Agricultural: EDR, RC-EDR, VLDR, RC-VLDR and RC-LDR; Interface/Wildland: RR, RD, RM and OS-RUR.
3. Commercial & Industrial Uses encompass: CR, CT, CO, LI, HI, BP, CC and MUPA. Public Facilities & Infrastructure Uses encompass: PF, FWY and MISC. (FWY and MISC are not LUDs, rather they denote existing uses of land and/or GIS mapping categories only.)
4. Natural Resource Uses encompass: Rural/Agricultural: AG and OS-MIN; Interface/Wildland: OS-REC.
5. Open Space encompasses: OS-C, OS-CH, OS-W and VAC (VAC is an existing use of land designation, not a General Plan LUD).

6. Jobs/housing balance value from proposed Appendix F-1 and calibrated off the Board-approved RCP-10 SED data set used throughout the rest of this EIR for demographic values.

Source: SCAG, 2008. County Center for Demographic Research, 2010. Riverside County Planning Dept., Project application materials, 2013.

In terms of employment, build out of the current General Plan would also result in a roughly six-fold increase in the number of jobs available within Riverside County (from over 100,000 to nearly 600,000). This increase is cumulatively significant and was addressed under EIR No. 441 certified for the 2003 RCIP General Plan. Under the LUD changes proposed for GPA No. 960, the total number of jobs at build out would actually decrease slightly (to *566,000* ~~562,000~~). Thus, the project's incremental contribution to employment would be insubstantial. Under the cumulative build out scenario, the total number of jobs available from non-residential land uses (commercial, industrial, public facilities and natural resources) would also be slightly less (1.3%) than that of the current General Plan. When compared to the reduced growth potential of GPA No. 960, the cumulative scenario proposes greater growth and economic development from non-residential land uses through 25,000 additional jobs.

Overall, the land use reductions associated with either the project or the cumulative scenario would each contribute to fewer employment opportunities within Riverside County. This would worsen the jobs-to-housing imbalance, causing more people to leave Riverside County on a daily basis for employment. These commuters would increase in daily traffic, resulting in increased circulation impacts and contributing to air pollution in the region.

Compared to existing levels, the additional homes and population accommodated by the project, GPA No. 960, as well as those proposed under the cumulative build out scenario, would each contribute substantially to cumulatively significant direct and indirect population growth. In addition, the reduced numbers of jobs proposed under each of these two scenarios, particularly in relation to the large numbers of homes proposed, would also contribute substantially to the jobs/housing imbalance within Riverside County.

c. Impacts

Future development accommodated by the project will contribute incrementally to cumulative population and housing impacts as Riverside County builds out over time pursuant to the Riverside County General Plan (regardless of scenario). Specific impacts of the severities indicated will include the following:

(1) Cumulatively Substantial Impacts

- Induce substantial population growth within Riverside County, both directly (e.g., by proposing new homes and businesses) and indirectly (e.g., through the extension of roads and other infrastructure). This is particularly true of the new homes that would be constructed within previously vacant portions of Riverside County.

- Increase in the jobs-housing imbalance due to the construction of additional homes in excess of an equivalent number of employment-generating land uses (commercial, industrial, public facilities, etc.)

(2) Non-Substantial Incremental Impacts

- Small number of homes and their residents will be displaced where new development, particularly new highways and major roadways, is constructed on previously developed lands. Such displacements would be insubstantial, however, because of the existing and future housing inventories available within Riverside County for replacement. Displacement would not necessitate the construction of additional replacement housing elsewhere.

- As a result of population growth and new homes, in particular, the amount of roadways, storm drains, water reservoirs and storage tanks, pipelines, transmission lines and other infrastructure needed within Riverside County would also increase.

d. Mitigation

As described in detail in Section 4.3.4, a variety of existing regulations and policies would be implemented to avoid, reduce and minimize adverse impacts to population and housing. These include the following:

- General Plan Policies: LU 5.1, 5.2, 8.1, 9.4; C 1.1, 1.4, 1.5, 2.4, 3.16 and 7.9. See Section 4.3.4 for text of each.

- Riverside County Climate Action Plan: Proposed in conjunction with GPA No. 960. See Section 4.7.3 for full details.

e. Significance

The analysis above indicates that future development consistent with any of the General Plan build out analyzed, including the proposed project (GPA No. 960), would contribute mostly non-substantially to incremental impacts related to population and housing issues. However, even with mitigation, the project would contribute substantially to significant cumulative impacts stemming from the inducement of substantial population growth directly and indirectly. Build out of the cumulative General Plan scenario would do likewise. Due to the inherently growth-inducing and growth-accommodating nature of a General Plan, there is no feasible mitigation to fully reduce these cumulative impacts to below the level of significance. Thus, even though project effects would be individually limited, GPA No. 960's incremental contribution to cumulative housing and population impacts would be significant and unavoidable. Build out of the cumulative General Plan scenario would also result in significant and unavoidable cumulative impacts to population and housing within Riverside County.

3. Cumulative Effects on Aesthetics and Visual Resources

Section 4.4 (Aesthetics and Visual Resources) details the existing aesthetic and visual resources within Riverside County. It also analyzes aesthetic impacts that would arise from future development accommodated by the changes proposed by the project, GPA No. 960, as well as the mitigation necessary to ensure impacts are less than significant. As a result, areas already covered in Section 4.4 are not repeated here.

As noted in Section 4.4, aesthetic and visual resources include scenic vistas and viewsheds, scenic highways and scenic/visual resources, such as trees, rock outcroppings and elements of the built environment like historic buildings. It also addresses light and glare, which can adversely affect visual resources, ecosystems and the night-time use of the Palomar Astronomical Observatory (which relies on dark skies for scientific purposes). Section 4.4 includes a summary of Riverside County's aesthetic resources by "visual analysis area" (in Table 4.4-A), it also discusses glare, nighttime light and (in Table 4.4-B) scenic highways throughout Riverside County.

a. Existing Conditions

Visual Character: Because of its large size, Riverside County offers a great variety of visual resources, including scenic vistas, viewsheds and panoramic natural landscapes, as well as built environments, old and new, including numerous architectural features. Since 1999, when the Existing Setting Report was prepared for EIR No. 441

(for the 2003 RCIP General Plan), Riverside County's visual character has undergone substantial changes, particularly in the urban/suburban fringes, as growth fueled the urbanization of existing suburban areas and the conversion of open, vacant lands to developed uses. According to the State of California, Riverside County and its cities accounted for nearly a quarter of all new urban areas within California between 2006 and 2008. Between 2000 and 2008, the California Department of Conservation estimates that "developed or built-up land" in Riverside County increased by nearly 61,000 acres, much of it concentrated around existing city centers and other urban centers. Areas that have had considerable amount of visual changes associated with growth are noted in Table 4.4-A.

Nighttime Light, Glare and Palomar Observatory: Light pollution, i.e., the alteration of natural light levels in the outdoor environment due to artificial light sources, is most commonly taken to mean excessive or obtrusive artificial light. Artificial light pollution also includes "sky glow, glare, light trespass, light clutter, decreased visibility at night and energy waste," as well as incidental or obtrusive outdoor lighting, such as glare (visual impairment), trespass into areas not needing lighting, use when or where lighting is not needed and disturbance of the natural nighttime landscape. As a result, the visibility of stars and other natural night sky phenomena is decreased. Night lighting and glare can affect human vision, navigation and other activities. It also can lead to skyglow, which interferes with the operation of astronomical observatories, as well as with nocturnal wildlife, particularly night-hunting or foraging animals, such as owls and rodents.

A major scientific resource, the Palomar Observatory is located in San Diego County approximately 5.5 miles south of the Riverside County border. In order to minimize effects of nighttime light pollution within the region surrounding the observatory, the County of Riverside enforces Ordinance No. 655 (Regulating Light Pollution). This ordinance establishes two zones for specific lighting controls based on distance from the observatory: a 15-mile-radius sphere is denoted as "Zone A" and a "Zone B" encompasses a 15- to 45-mile radius from the observatory (see Figure 4.4.1 in Section 4.4). Special lighting restrictions apply within these zones.

Scenic Vistas, Highways and Roadways: Scenic vistas and natural features, including low-lying valleys, mountain ranges, ridgelines, rock formations, rivers and lakes are often enjoyed via Riverside County's many roadways. Due to the visual significance of many of these areas, certain roadways within Riverside County have been officially recognized as either "eligible" or "designated" State or County scenic highways. Section 4.4 includes Table 4.4-B and Figure 4.4.2 describing these highways. Development along designated scenic highways and roadways is managed to preserve the areas' scenic qualities.

b. Future Conditions

Light and Glare: Table 5.5-F (Cumulative Palomar Lighting Zone Effects), below, shows how each of the General Plan build out scenarios, including cumulative, would incrementally affect light and glare levels within Riverside County relative to the Palomar Special Lighting Zones established under Riverside County Ordinance No. 655. Due to its proximity, excessive lighting from future development occurring within Zone A in particular has the greatest potential to incrementally affect observatory operations. Because of the additive nature of light, such incremental contributions would be cumulatively significant.

As shown in the table, the main changes to the General Plan as a result of the project, GPA No. 960, would spare roughly 6,200 acres of land in Zone A, the most light-sensitive zone, by preserving this land as vacant or open space and reducing development potential in interface/wildlands by an equivalent amount. Within Zone B, the project's changes would add *over* ~~nearly~~ 4,000 acres of development potential within built areas (urban/suburban, rural/agriculture and public facilities). This increase, however, is offset by a reduction of nearly 8,000 acres in interface/wildlands development potential and an increase of over 4,000 acres of vacant/open space areas.

Nevertheless, overall the project's incremental contribution to cumulative light and glare impacts would be considerable.

Footnotes:
1. The Palomar Astronomical Observatory is located in San Diego County, approximately 5.5 miles south of the Riverside County border.
2. These are the acreages that indicated scenario would contribute to build out impacts, *in addition* to those associated with build out of the current (*2009* ~~2008~~) General Plan (which are shown under "CURR GP Total"). *Also see Tables 2.1, 2.2 and 2.3 in Appendix EIR-11 for more detailed data.*
3. For details on the specifics of each scenario, see Table 5.5-D. All values rounded to nearest 10 acres.

Source: Riverside County GIS *(RCIT)*, RCLIS layer (Palomar Special Lighting Zones) and Project Application Data, 2013 *and 2014*.

Under the Cumulative scenario, General Plan build out would result in nearly an additional 7,000 acres of development within Rural/Agricultural areas in Zone A and roughly 3,600 acres of Urban/Suburban in Zone B, with corresponding decreases in development in Interface/Wildland areas. Lastly, for all of the build out scenarios, the largest amount of vacant lands lost would be in Zone B, particularly due to the roughly 300,000-acre increase in Interface/Wildland areas that would result under the current General Plan, as well as the other two build out scenarios. For these reasons, all of the build out scenarios would have cumulatively considerable impacts on light and glare effects.

Scenic Vistas, Highways and Roadways: Growth pressures within Riverside County will result in development that causes the incremental loss, fragmentation and degeneration of the natural viewsheds and vistas within Riverside County, regardless of the General Plan build out scenario. To examine the potential effects of General Plan build out on scenic highways, spatial analysis was performed to determine the amount of future development that could occur within proximity of these resources under each of the scenarios examined. As shown in Table 5.5-G (Cumulative Scenic Highway Effects), growth within Riverside County would result in encroachment of developed uses into areas within the viewsheds of a variety of State- and County-designated and eligible scenic highways and related scenic vistas.

Per Table 5.5-G, build out of the existing General Plan will contribute incrementally to the loss of natural scenic resources and viewsheds along scenic highways and vistas within Riverside County and result in varying degrees

of incremental impacts, depending on the size, scope and location of the incremental development proposed. Within proximity to State-designated scenic highways, interface/wildland areas would see the greatest increase in development potential (roughly 10,000 acres); rural/agricultural areas would also see a roughly three-fold increase as well. The amount of land devoted to public facilities would decrease slightly, but the increased development would occur mainly at the expense of available vacant and open space lands. Since much more land is in proxymity to State-eligible and County-eligible scenic highways, this pattern of development potential increasing in urban/suburban and rural/agricultural areas at the expense of vacant and open space lands is even more pronounced. In particular, development potential within interface/wildland areas greatly increases under the existing General Plan. Proposed changes from both the project and for the cumulative scenario slightly lessen these increases, but the overall impact on scenic resources is still significant. Similar trends occur for both the project and cumulative General Plan build out scenarios. In areas with scenic resources, development potential for urban/suburban uses would increase by roughly 9% and 6%, respectively. For these reasons, even without the proposed project, build out of the General Plan would result in cumulatively significant impacts to scenic highways and vistas. Overall, however, both the project and cumulative General Plan build out scenarios would also contribute significantly to cumulative impacts to scenic vistas, viewsheds and scenic highway views.

c. Impacts

Future development accommodated by the project will contribute incrementally to cumulative aesthetic impacts as Riverside County builds out over time pursuant to the Riverside County General Plan (regardless of scenario). Specific impacts of the severities indicated will include the following:

Footnotes:

1. Within 2,500 feet (roughly one-half mile).
2. Encompass the following roadways; see Table 4.4-B (section 4.4) for descriptions of the specific segments.
   State Designated Scenic Highways: Portions of State Routes 62, 74 and 243.
   State Eligible Scenic Highways: Portions of Interstates 10 and 15, and State Routes 71, 74, 79, 91 and 111.
   County Eligible Scenic Highways: Portions of Interstates 10 and 215, U.S. Highway 95, State Route 79, and portions of Dillon Rd., Oak Glen Rd., Beaumont Ave., San Timoteo Canyon Rd., Redlands Blvd., Gilman Springs Rd., Ramona Expressway, Cajalco Rd., El Sobrante Rd., Mockingbird Canyon Rd. and La Sierra Ave.
3. These are the acreages that indicated scenario would contribute to build out impacts, *in addition* to those associated with build out of the current (*2009* ~~2008~~) General Plan (which are shown under "CURR GP Total"). *Also see Tables 4.1, 4.2 and 4.3 in Appendix EIR-11 for more detailed data.*
4. For details on the specifics of each scenario, see Table 5.5-D. All values rounded to nearest 10 acres.

Source: Riverside County GIS *(RCIT)*, RCLIS layer (Scenic Highways) and Project Application Data, 2013 *and 2014*.

(1) Cumulatively Considerable Impacts

- In addition to infill, future development would result in the physical conversion of open space, vacant and agricultural lands to more urban types of uses, incrementally affecting scenic vistas and leading to cumulatively substantial impacts to these resources. See similar discussion under Impact 4.4.A.

- The extension of roadways and infrastructure into previously undeveloped areas, particularly into undisturbed wildlands, would add incrementally to visual impacts. Long, linear improvements, such as roads and powerlines, can be particularly noticeable in open vistas. Where located in, or immediately adjacent to, large expanses of scenic open space, future development could have major visible aesthetic effects, particularly for sites with limited or no existing access ways that would require road construction, leading to cumulatively considerable impacts.

- Development would incrementally damage scenic resources, including, but not limited to, trees, rock outcroppings and historical buildings within a State scenic highway. Where located along a designated or eligible scenic highway, scenic vista or other scenic resource, these incremental impacts could substantially impair the aesthetics of the resource. See similar discussion under Impact 4.4.B.

- Future development would create new sources of light and glare that would adversely affect day or nighttime views in the areas. Lighting associated with higher intensity and density uses will increase nighttime light levels and daylight glare effects on sensitive areas, such as residences and natural habitat areas. See similar discussion under Impact 4.4.D.

(2) Non-Substantial Incremental Impacts

- Future development per any of the build out scenarios would contribute incrementally to changing the visual character of Riverside County over time.

- Development would also contribute to the overall increase in light levels and skyglow within the county. Where development occurs in Special Lighting Zone A or B, additional light sources would contribute incrementally to interference with the nighttime use of Palomar Observatory.

d. Mitigation

As described in detail in Section 4.4.6, a variety of existing regulatory compliance and specific mitigation measures would be implemented to avoid, reduce and minimize adverse cumulative impacts to aesthetics and visual resources within Riverside County. These include the following items:

(1) Regulatory Compliance

Key Regulations and Programs: See Section 4.4.6 for detailed information on how each of the following items contributes to avoiding, reducing or minimizing cumulative impacts.

- California Scenic Highway Program (CalTrans)
- Ordinance No. 655 - Regulating Light Pollution
- Ordinance No. 460 - Regulating the Division of Land
- Ordinance No. 461 - Road Improvement Standards and Specifications
- Ordinance No. 655 - Regulating Light Pollution
- Ordinance No. 915 - Regulating Outdoor Lighting
- Riverside County Design Guidelines

Key General Plan Policies: See Section 4.4.3 for text of each policy.

- Land Use Policies: LU 4.1, 4.5, 14.3 - 14.8, 16.4, 16.5, 16.12, 19.1, 28.6, 28.10, 29.9, 30.8 and 31.5.
- Circulation Policies: C 5.3, 19.1 and 20.1.
- Open Space Policies: OS 9.3 and 9.4.

(2) CEQA Mitigation

Existing Mitigation Measures: As part of EIR No. 441 certified for the RCIP General Plan adopted in October 2003, the following mitigation measures (MMs) would apply for future development.

- **Existing MM 4.4.1A:** Development projects shall be subject to the requirements of all relevant guidelines, including the community center guidelines, Riverside County supervisorial district guidelines and all applicable standards, policies and/ or regulations of the County of Riverside or other affected entities pertaining to scenic vistas and aesthetic resources. Factors considered in these guidelines include the scale, extent, height, bulk or intensity of development; the location of development; the type, style and intensity of adjacent land uses; the manner and method of construction, including materials, coatings and landscaping; the interim and/or final use of the development; the type, location and manner of illumination and signage; the nature and extent of terrain modification required; and the potential effects to the established visual characteristic of the project site and identified scenic vista or aesthetic resource.
- **Existing MM 4.4.2A:** Riverside County shall require that sources of lighting within the General Plan area be limited to the minimum standard required to ensure safe circulation and visibility.
- **Existing MM 4.4.2B:** Riverside County shall require street lighting to be limited to intersections and other locations that are needed to maintain safe access (e.g., sharp curves).

- **Existing MM 4.4.2C:** Riverside County shall require exterior lighting for buildings to be of a low profile and intensity.
- **Existing MM 4.4.2D:** The County [of Riverside] shall establish a liaison with California Institute of Technology [which operates the Palomar Observatory] to ensure "dark skies" preservation procedures are incorporated, as necessary, in future [Riverside] County ordinances.
- **Existing MM 4.4.2E:** The County [of Riverside] shall participate in Mount Palomar [*sic*] Observatory's "dark sky" conservation area.

New Mitigation Measures: As part of EIR No. 521, the following new mitigation measure (MM) is proposed to reduce aesthetic impacts.

- **New MM 4.4.A-N1:** No development shall be approved for parcels without adequate legal access and adequate physical access. Adequate and accessible circulation facilities must also exist to meet the demand of the proposed land use.

e. Significance

Implementation of all of the above regulations, General Plan policies and mitigation measures, would be sufficient to ensure that all of the incremental (non-substantial) cumulative impacts listed above would be less than significant. For the substantial impacts listed above, however, even with the existing and additional mitigation indicated, the cumulative impacts associated with build out of any of the above General Plan scenarios would be significant and unavoidable.

4. Cumulative Effects on Agriculture and Forestry Resources

Section 4.5 (Agricultural and Forestry Resources) of this EIR discusses existing agricultural and forestry resources within Riverside County, as well as the sources used (and any updates made to them) for this data. The section also analyzes the agricultural impacts that would arise from future development accommodated by the changes proposed by the project, GPA No. 960, as well as the mitigation (both through regulatory compliance and CEQA-specific mitigation) necessary to ensure impacts are less than significant. As a result, areas already covered in Section 4.5 are not repeated here; see that section directly for additional resource details.

Included in Section 4.5 are data and statistics on cultivated crops, State-designated farmlands and forestry areas, specifically: Table 4.5-A **(**Cultivated Crop Production Statistics), Table 4.5-B **(**Other Agricultural Product Valuation Data), Table 4.5-C **(**Crop Valuation by Agricultural District), Table 4.5-D (State-Designated Farmland Data for Riverside County), Table 4.5-E (Project Effects on Agriculture Land Use Designations in the General Plan), Table 4.5-F (Project Effects on Lands in Agricultural Use), Table 4.5-G (Effects on State-Designated Farmlands) and Table 4.5-H (Project Relationship to Existing Agricultural Preserves). It also includes Figure 4.5.1 (Agricultural Resources Map) and Figures 4.5.2 and 4.5.3 (High-Elevation Forestry Resources for Western and Eastern Riverside County, respectively).

a. Existing Conditions

Agriculture: The wide variety of climates and soil types within Riverside County allows a diverse array of crops to be grown. Agricultural resources include lands cultivated for crops for both human and animal use, providing livestock forage or as a source of fiber or other raw materials, as well as non-cultivation (ranch) activities, such as

livestock for meat, milk and dairy products, and fiber and other non-edible products (wool, leather, etc.). Also in this category are aquaculture (fish farms) and poultry (producing poultry meat, eggs, chicks) and other products. Historically, agricultural production has occurred in western Riverside County along Temescal and Perris valleys, though both areas have been under increasing urbanization pressures in recent years. Agriculture still thrives in southwestern Riverside County, particularly in the wine country of Temecula Valley. It is even more prominent in eastern Riverside County in areas such as the Coachella Valley and, in particular, the Palo Verde Valley area. Although there are state-designated Farmlands (i.e., Prime Farmland, Unique Farmland and Farmland of Statewide Importance) throughout Riverside County, agricultural activities are not limited to these areas.

Forestry: There is no commercial forestry or timber production industry within Riverside County other than Christmas tree farms of nursery stock production (that is, cultivated rather than wild-harvested plants). Riverside County's forestry resources do, however, play a vital role in establishing the character of Riverside County. The Cleveland National Forest frames southwestern Riverside County and the San Bernardino National Forest frames edges of eastern Riverside County; both forests fall within the Sierran montane range. These ranges are characterized by winter snows and summer fires, large conifers (pine and fir trees) and a great diversity of animal species. Per the State of California, no "California forest land" ownership, either public or private, is mapped for Riverside County, although some coniferous forests do occur within Riverside County. At lower elevations (generally below 5,000 feet), these forests commonly border mixed evergreen forest, oak woodland and chaparral. According to Cal Fire (2003), there are no fixed commercial timber operations subject to a Timber Harvesting Plan in Riverside County. The County of Riverside does, however, participate in a "woody biomass utilization program" funded by the U.S. Forest Service and run by CalFire (Riverside Unit).

b. Future Conditions

Spatial analysis was performed to examine the cumulative results of General Plan build out on agricultural and forestry resources. To encapsulate the scope of impacts resulting from build out of the Riverside County General Plan, the various General Plan cumulative build out scenarios were analyzed against the state-mapped farmlands (i.e., Figure 4.5.1) and mature forests within Riverside County (i.e., Figures 4.5.2 and 4.5.3). Table 5.5-H (Cumulative Farmland Effects) shows the cumulative conditions for impacts to farmlands for the three General Plan build out scenarios examined in this section (CURR GP, GPU/GPA960 and CULM GP, see Section 5.5.1 for specifics on each).

Cumulative effects of General Plan build out were compared to the farmland mapping data from the State Department of Conservation and several trends were noted. The amount of Prime Farmland lost to urban/suburban development would increase nearly 250% under the existing General Plan. For both the project (GPU/GPA960) and cumulative (CULM) General Plan build out scenarios, Prime Farmlands lost to urban/suburban development would increase by roughly 12% and *20%* ~~23%~~, respectively. Both these losses are cumulatively considerable. Rural/agricultural lands designated as Prime Farmland would also be lost *as the County develops over time*, though in incrementally insignificant amounts ~~(1.4% and 2.1%, respectively)~~. *However, compared to the existing General Plan, both the project and cumulative General Plan scenarios would affect slightly (1-2%) less Prime Farmland.* The amount of vacant/open land would decrease roughly 80% under the existing General Plan, but *either* the project *or* ~~and~~ cumulative scenario~~s~~ would lessen these losses by roughly 10% ~~each~~. The other types of designated farmlands show similar trends. These development trends would have similar incremental effects on existing agricultural preserves and result in incremental land use conflicts between agricultural and non-agricultural uses.

For forestry resources, see Table 5.5-M (Cumulative Biological Effects) for data on cumulative effects to woodland and forest acreage throughout Riverside County. Since forestry resources within Riverside County are tracked according to these habitat types, the table is not repeated here. Data in Table 5.5-M indicate that land use changes occurring as the General Plan builds out (regardless of scenario) will affect only sporadic or occasional

stands of forest vegetation at altitudes above 5,000 feet sea level. This includes stands of "Montane Hardwood" and "Montane Hardwood-Conifer Forest," primarily in the San Jacinto Mountains of central Riverside County. None of these forest resources, however, supports industrial or commercial timber production. Overall, neither the project (GPU/GPA960) nor the cumulative (CULM) build out scenarios would result in significant cumulative forestry impacts.

These are the acreages that indicated scenario would contribute to build out impacts, *in addition* to those associated with build out of the current (*2009* ~~2008~~) General Plan (which are shown under "CURR GP Total"). *Also see Tables 5.1, 5.2, 5.3 and 5.4 in Appendix EIR-11 for more detailed data.*

Source: Riverside County GIS *(RCIT)*, RCLIS layer (State Farmland Mapping & Monitoring Program) and project application data, 2013 *and 2014*.

c. Impacts

Future development accommodated by the project will contribute incrementally to cumulative agricultural and forestry impacts as Riverside County builds out over time pursuant to the Riverside County General Plan (regardless of scenario). Specific impacts of the severities indicated will include the following:

(1) Cumulatively Considerable Impacts

- Direct loss due to the incremental conversion of state-designated Farmlands to non-agricultural uses over time. See discussion under Impact 4.5.A.
- Growth pursuant to General Plan build out (any scenario) would indirectly result in additional development and infrastructure demand that would further conversion of designated Farmlands to urban uses and result in other changes in the existing environment leading to additional Farmland conversion.
- Some incremental growth would encroach on or conflict with existing agricultural zoning, agricultural uses, land subject to a Williamson Act contract and land within Riverside County Agricultural Preserves. See discussion under Impact 4.5.B.
- Additional growth would also result in further conversion of agricultural lands to urban uses, encroach on existing agricultural activities and mapped farmlands, and result in other changes in the existing environment leading to additional farmland conversion.
- Growth would result in development of non-agricultural uses within 300 feet of agriculturally zoned property, as well as other environmental changes that, due to their location or nature, would result in the conversion of farmland to non-agricultural use.

(2) Non-Substantial Incremental Impacts

- Encroachment of residential and other urban-density land uses into agricultural areas would result in incremental impacts due to agricultural nuisances (dust, odors, noise, flies, soil or groundwater contamination, chemical overspray and runoff exposure, etc.).

- For farmers, urban encroachment would adversely affect the efficiency of remaining farming operations due to increased air pollution, livestock predation by pets, crop diseases, etc., as well as water scarcity, theft, crop pilferage, farm trespass and the like.

- Future development would incrementally result in the loss or conversion of forest land to non-forest uses, as well as other changes in the existing environment which, due to their location or nature, could result in forest land conversion as well.

- Growth would indirectly result in additional development and infrastructure demand that would create additional potential for forest land conversion or encroachment of incompatible land uses.

- Growth would also involve other incremental changes that could result in conversion of forest land to non-forest use. This includes incremental loss of oak trees and other mature forest canopy, either through direct take or through indirect causes, such as hydrological changes, etc.

d. Mitigation

As described in detail in Section 4.8.3, a variety of measures would be implemented to avoid, reduce and minimize adverse cumulative agricultural and forestry impacts. These include the following regulatory compliance measures:

Key Regulations and Program: See Section 4.8.3 for details on each regulation.

- California Land Conservation Act (aka "Williamson Act")

- California Timberland Productivity Act California Forest Practice Act

- Ordinance No. 509 - Establishing Agricultural Preserves

- Ordinance No. 559 - Regulating the Removal of Trees

- Ordinance No. 625 - Right To Farm

- Riverside County Rules and Regulations Governing Agricultural Preserves

Key General Plan Policies: See Section 4.8.3 for the text of each policy.

- Land Use Policies: LU 7.6, 7.10, 20.1, 20.2 and 20.4 - 20.11

- Open Space Policies: OS 7.1, 7.3 - 7.5, 8.1, 8.2 and 9.4

e. Significance

The analysis above indicates that future development consistent with any of the General Plan build out analyzed, including the proposed project (GPA No. 960), would contribute non-substantially to incremental impacts to forestry resources and uses in Riverside County. However, even with mitigation, growth within Riverside County pursuant to any of the General Plan build out scenarios, including that of the project (GPA No. 960), would contribute substantially to significant cumulative agricultural impacts. These include direct and indirect

conversion of designated farmlands, as well as encroachment on existing agricultural uses. General Plan build out would also result in the "significant conversion of active agricultural land and agricultural soils to non-agricultural uses." Due to the inherently growth-inducing and growth-accommodating nature of a General Plan, there is no feasible mitigation to fully reduce these cumulative impacts to below the level of significance. Thus, even where impacts from future implementing project effects would be individually limited, GPA No. 960's incremental contribution to cumulative agricultural impacts would be significant and unavoidable.

5. Cumulative Effects on Air Quality

Section 4.6 (Air Quality) of this EIR discusses specifics regarding existing and future air pollution levels within Riverside County. It also analyzes the impacts that would arise from future development accommodated by the changes proposed by the project, GPA No. 960, as well as the regulatory mitigation measures that would ensure impacts are less than significant or at least reduced to the extent feasible. Thus, to avoid repetition, information already covered in Section 4.6 is not repeated here. The reader is encouraged to refer back to that section directly for additional details on air pollution.

Section 4.6 of this EIR provides a complete description of the ambient air quality in Riverside County, as well as analysis of the existing and future air quality impacts projected to occur as Riverside County builds out. This data includes Table 4.6-A (Ambient Air Quality Reporting for Criteria Pollutants – SCAB, 2007-2009), Table 4.6-B (Ambient Air Quality Reporting for Criteria Pollutants – SSAB, 2007-2009), Table 4.6-C (Emission Thresholds for Air Basins within Riverside County), Table 4.6-D (Typical Project Construction Emission Estimates), Table 4.6-E (Comparison of Unmitigated Project Operational Emissions – SCAQMD, Table 4.6-F (Comparison of Unmitigated Project Operational Emissions – MDAQMD, Table 4.6-G (Mitigated Net Project Operational Emissions – SCAQMD), Table 4.6-H (Mitigated Net Project Operational Emissions – MDAQMD), Table 4.6-I (Localized Significant Analysis for 5 Acre Site – Construction), Table 4.6-J (Localized Significant Analysis for 5-Acre Site – Operational). It also includes Figure 4.6.1 (Air Basins in Riverside County).

a. Existing Conditions

Riverside County spans three different air basins: South Coast (SCAB), Salton Sea (SSAB) and Mojave Desert (MDAB). The portions of Riverside County within the South Coast and Salton Sea Air Basins are regulated by the South Coast Air Quality Management District (SCAQMD). The easternmost third of the county, within the Mojave Desert Air Basin, is under the jurisdiction of the Mojave Desert Air Quality Management District (MDAQMD). Each of the three air basins covering Riverside County have unique characteristics affecting regional air quality. The climate and meteorology of each air basin, as well as their effects on air quality, detailed in Section 4.6.2.

Air pollutant emissions within the air basins are generated from stationary, mobile and natural sources. Stationary sources occur as point and area sources. Point sources occur at an identified location and are usually associated with manufacturing and industry. Area sources are widely distributed and arise from many small emissions. Among others, construction activities that create fugitive dust, such as excavation and grading, contribute to area source emissions. Mobile sources refer to emissions from on- and off-road motor vehicles, including tailpipe and evaporative emissions. On-road sources are vehicles operated on roadways and highways. Off-road sources include vehicles not operated on roads, as well as aircraft, trains and construction equipment. Mobile sources account for the majority of the air pollutant emissions within most air basins. Air pollutants can also be generated by the natural environment, such as when fine dust particles are pulled off the ground surface and suspended in the air during high winds.

To protect the public health and welfare, the federal and state governments identified five criteria air pollutants and a host of air toxics that have established ambient air quality standards through the federal Clean Air Act and the California Clean Air Act. Air pollutants are typically classified as primary or secondary pollutants. The criteria pollutants carbon monoxide (CO), particulate matter (PM), sulfur dioxide (SO_2) and lead (Pb) are considered primary pollutants because they are emitted directly into the atmosphere. Ozone (O_3) is considered a secondary pollutant because it is not directly emitted but formed through a photochemical reaction in the atmosphere when reactive organic gases (ROGs) and nitrogen oxides (NO_X) combine in the presence of sunlight and produce O_3. Both the federal and state governments have established ambient air quality standards for outdoor concentrations of various pollutants in order to protect public health. See Section 4.6.2 for details on each criteria pollutant, as well as discussions of toxic air contaminants (TACs) and odors. See Tables 4.6-A and 4.6-B in Section 4.6 for detailed air quality data for the basins with Riverside County and Section 4.6.4 for specifics on construction, operation and other emissions thresholds.

At the federal level, SCAB is designated as "extreme nonattainment" for ozone and "serious nonattainment" for PM_{10}. SCAB's federal status for CO was recently upgraded from nonattainment to "serious maintenance area." It is also in federal nonattainment for $PM_{2.5}$, but is in attainment for NO_2 and SO_2. At the state level, SCAB is designated "extreme nonattainment" for ozone and also in nonattainment for particulates $PM_{2.5}$ and PM_{10}. It is in attainment for the State of California's CO standard and for SO_2 and NO_2, a subcategory of NO_X. In an effort to monitor the various concentrations of air pollutants throughout the basin, the SCAQMD has divided the region into 38 source receptor areas (SRAs), which are tracked by 32 monitoring stations. Ambient air data are provided in the tables in Section 4.6.2.

MDAB is designated as "severe nonattainment" for ozone, nonattainment for PM_{10}, "unclassified/attainment" for $PM_{2.5}$ and attainment for CO, NO_2 and SO_2 at the federal level and at the state level "moderate non-attainment" for ozone and "nonattainment" for PM_{10} and $PM_{2.5}$. It is in state attainment for CO and NO_2, and attainment/unclassified for SO_2. The MDAQMD also monitors air quality within the MDAB, but does not have a monitoring station within the Riverside County portion of the basin.

In regards to air toxics, CARB has produced a series of estimated inhalation cancer risk maps based on modeled levels of outdoor composite toxic pollutant levels. Its 2010 estimated map indicates the majority of Riverside County is exposed to a theoretical inhalation cancer risk of less than 250 persons per million. However, the northwestern portion of Riverside County that includes portions of the Jurupa, Highgrove, Eastvale, Reche Canyon and Temescal Area Plans are exposed to inhalation cancer risks of greater than 250 persons per million. These risk maps depict theoretical inhalation cancer risk due to modeled outdoor toxic pollutant levels and do not account for cancer risk due to other types of exposure. The largest contributors to inhalation cancer risk are diesel engines.

b. Future Conditions

The location and densities of development and other human activities affect the amount of air pollutants generated. When land uses are spread throughout a community, they tend to increase the number and length of motor vehicle trips and associated air pollutant emissions because of the limited opportunities to walk, ride bicycles and use public transportation between uses, at homes and work or shopping. Smaller, more compact, higher density uses tend produce less air emissions from vehicle trips, as well as natural gas, on a per-unit basis. The following data *addresses* ~~discuss~~ both short-term (construction) and long-term (operational) emissions, as well as toxic air contaminants and local effects.

Construction Emissions: As outlined in Section 4.6.5.B.1, construction emissions are site-specific and thus will vary depending on the particulars of the implementing project. Because construction factors can vary so widely,

estimating all of the construction emissions or impacts for any of the Riverside County build out scenarios is infeasible. Instead, Table 4.6-D in Section 4.6 shows examples of the construction emissions associated with various sizes of development projects. The table demonstrates the construction emissions that would result from onsite grading activities, transport of materials to and from the site and the actual building construction, painting and paving associated with the individual developments. Most notably it shows that SCAQMD and MDAQMD thresholds for PM_{10} will be exceeded when construction activities result in the disturbance of 25 or more acres at a time. In addition, the construction of 150 single-family residential units or more would also exceed the SCAQMD threshold for ROG.

Because of the ease with which individual projects can exceed regulatory thresholds, construction air quality impacts would likely be considered individually significant for many of these future projects. Further, since the precise timing of future development cannot be controlled or readily foreseen, it is possible multiple projects would undergo construction simultaneously. The result would be cumulatively considerable, even if the individual projects were individually below the thresholds. Thus, for these reasons, construction air quality impacts are considered cumulatively considerable for any of the General Plan build out scenarios addressed.

Operational Emissions: Air quality effects are most often determined on the basis of traffic patterns which reflect land use, population and employment sources. Air quality effects are also influenced by growth projections and patterns. For the project and cumulative build out scenarios (i.e., GPU/GPA960 and CULM scenarios), operational emissions were calculated using URBEMIS for stationary and mobile source emissions. Scenario-specific data for the types and amounts of land use development planned were entered into URBEMIS to determine the pollutant emissions anticipated at full build out. This data includes the number of residential dwelling units, square footage of non-residential land uses, average daily trips, vehicle miles traveled and average trip lengths. Where project-specific data was not available, URBEMIS defaults were used. The result of the modeling indicates estimated air quality impacts for a variety of future scenarios, including each of the General Plan build out scenarios proposed for this cumulative analysis. For specifics on how the air quality data was modeled, see Section 4.6.4 and the letter addendum issued by Atkins, dated July 2013 (see Appendix EIR-10). The threshold values analyzed in Tables 5.5-I and 5.5-J, below, are as established by the agencies indicated. For a full listing of threshold standards, see Table 4.6-C in Section 4.6.3.

Footnotes:
1. All values (except thresholds) rounded to nearest 10. Thus, totals may not sum precisely.
2. All build out scenarios calculated for 2040, the limit for URBEMIS2007 results. Although build out is anticipated for 2060, well beyond 2040, use of 2040 represents a conservative approach. See Appendix EIR-11, *Tables 6.1 – 6.4*. No data available for existing General Plan build out (CURR GP scenario).
3. Thresholds established by agency listed. Emission is significant ("yes") if net emission exceeds this value.
4. *From ~~Source:~~* Table 4.6-E for SCAQMD, Table 4.6-F for MDAQMD.
5. *From ~~Source:~~* Table *AQ-1* ~~Add-1~~ for SCAQMD and Table *AQ-2* ~~Add-2~~ for MDAQMD from Atkins Letter Addendum, *December 2014* ~~July 2013~~.
6. Net emissions are build out scenario minus existing year emissions.

Source: Atkins, Air Quality Study for General Plan Update, 2011; Atkins, Letter Addendum, *December 2014* ~~July 2013~~. (See Appendix EIR-10)

Table 5.5-J (Cumulative Unmitigated Operational Emissions) shows the anticipated unmitigated emissions for the various build out scenarios, and Table 5.5-K (Cumulative Mitigated Operational Emissions) shows the same results after reductions derived from proposed mitigation. Note that the build out scenario for the existing (*2009* ~~2008~~) General Plan was not modeled since it was not one of the proposed project outcomes and its results would only provide a plan-to-plan comparison. As indicated in the tables below, all of the build out scenarios would result in net emissions exceeding SCAQMD and MDAQMD thresholds of significance for CO, ROG, SO_X, PM_{10} and $PM_{2.5}$ but would be less than significant for NO_X emissions. The negative net emissions associated with NO_X reflects the substantial decrease in anticipated emissions from vehicles resulting from state and federally mandated vehicle efficiency increases over time.

Localized Significance Thresholds (LSTs): Localized significance thresholds (LSTs) were developed by the SCAQMD to determine maximum allowable concentrations of criteria air pollutants during construction or operation for individual developments. Due to the programmatic nature of the General Plan and the proposed project, detailed construction phasing, equipment and intensities are not available for the development area. Further, the exact size and location of future development within Riverside County is unknown at this time.

Therefore, a countywide build out analysis of impacts to sensitive receptors and population groups cannot be accurately determined using LST analysis and would be inappropriate under the SCAQMD's LST methodology, because specific acreages, uses and distances to sensitive receptors are required in order to calculate localized pollutant concentrations at sensitive receptors. For reference, however, the LST emissions associated with "typical" construction and operation activities are presented in Tables 4.6-I and 4.6-J of Section 4.6.5.

Toxic Air Contaminants: In addition to criteria pollutant analysis, localized emissions of toxic air contaminants (TACs) are also of concern with respect to sensitive receptors. Sources of TACs include diesel particulate matter from railroads, emissions from the combustion of airplane fuel, benzene emissions in close proximity to gasoline dispensing stations, dry cleaners and film processing services that use perchloroethylene, auto body shops due to various solvents, furniture manufacturers and repair facilities that use methylene chloride and print shops that use various solvents. The primary source of TACs within Riverside County is diesel-fueled trucks and other vehicles traveling the freeways and major roadways. In 2005, CARB published the "Air Quality and Land Use Handbook – A Community Health Perspective," to provide guidance on how to analyze TAC emissions. The CARB Guidance recommends buffer zones to insulate sensitive receptors from TAC sources.

Due to the programmatic nature of the various General Plan build out scenarios, it is not possible to forecast the detailed construction phasing, equipment and intensities, as well as project size, timing, etc., necessary to model LSTs or TACs with any degree of accuracy or reliability. It can be assumed, however, that various sizes and types of project will be developed. And because of the increased densities planned on the General Plan land use maps and the stated desire for residential land uses to be developed close to both transit and commercial centers (to reduce vehicle miles driven in the county, to improve regional air quality), it can be assumed that both the construction and the operation of commercial and industrial sources would be developed relatively close to sensitive receptors, including residences, schools and medical facilities. Since TACs are measured based on their *localized* significance relative to exposure of adjacent or nearby sensitive receptors, however, a cumulative level of significance cannot be assigned to such values; they are only cumulatively significant in terms of localized contributions. Such localized contributions cannot be calculated at the programmatic level.

c. Impacts

As discussed in greater detail in Section 4.6, future development will contribute incrementally to cumulative air quality impacts as Riverside County builds out over time pursuant to the General Plan (regardless of the scenario). Specific impacts will include the following:

(1) Cumulatively Considerable Impacts

- Relative to the 2008 SCAG Regional Comprehensive Plan and Guide (RCP), the existing (*2009* ~~2008~~) General Plan would be consistent because it predates the projections used in the RCP and the RCP includes this county build out scenario in its forecasts. For the project scenario (build out of the General Plan as amended by GPA No. 960), the build out capacity, populations and overall densities are reduced compared to that of the current General Plan. However, when gaged against the existing conditions, build out of the General Plan with the project would result in a cumulatively considerable impact. The same holds for the cumulative build out scenario. The CULM scenario represents increases in capacity, density, land uses and populations that greatly exceed that of the current General Plan. As such, its incremental contributions would result in cumulatively considerable conflicts with the regional air quality plans.

- As demonstrated by Table 4.6-D, both individual and cumulative emissions from future development, including that accommodated by the proposed project, GPA No. 960, would have the potential to exceed

construction emission thresholds (see Table 4.6-C). Thus, incremental emissions from build out of any of the General Plan scenarios, including that encompassing the project (GPU/GPA960), have the potential to be cumulatively significant.

- Construction equipment emit both criteria pollutants and diesel particulate matter (DPM), which is a toxic air contaminant (TAC), and construction activities such as grading generate fugitive dust emissions, including PM_{10} and $PM_{2.5}$. The cumulative emissions of criteria pollutants and DPM resulting from all construction activities throughout Riverside County will have the potential to affect the health of residents within Riverside County. In the absence of data to prove otherwise, it is assumed that future development accommodated by the proposed project would result in varying incremental amounts of construction on a daily and annual basis through that would be cumulatively significant, even if individually consistent with applicable construction thresholds, for any of the General Plan build out scenarios, including that encompassing the project (GPU/GPA960).

- Stationary and mobile sources would emit criteria pollutants based on the level of daily operation. Modeling results indicate that such emissions would be large, both for the project, GPA No. 960 (see Impact 4.6B(2) in Section 4.6) and cumulatively for any of the General Plan build out scenarios due to hundreds of individual sources that would be developed across Riverside County. Even with mitigation through regulatory compliance and CEQA-specific mitigation measures (from both this EIR and the prior EIR No. 441), operational criteria pollutant emissions would still cumulatively exceed regulatory thresholds. Thus, this impact would be cumulatively considerable.

- As discussed in Impact 4.6.B of Section 4.6, even when individual projects can mitigate construction or operational impacts to below regional thresholds, when emissions from all of the individual developments are considered together as one project, the regional thresholds would be exceeded as shown in Tables 4.6-E and 4.6-F. The measures outlined in Impact 4.6.B would aid in reducing cumulative impacts. However, the mitigated emissions shown in Tables 4.6-G and 4.6-H demonstrate that combined emissions associated with GPA No. 960 are above the thresholds of significance, and even with the implementation of reductions, emissions of criteria pollutants are not reduced to below regulatory thresholds due to the level of residential and non-residential growth. Therefore, impacts associated with future development accommodated by the project would be cumulatively considerable and result in a significant and unavoidable impact. Impacts would be similarly considerable for build out of the CULM scenario as well.

- Future development will expose sensitive receptors (residence, school, hospital, etc.) to air pollutant emissions from both construction and operational activities. Such impacts are generally localized to just the sensitive receptors surrounding the emission source. On a cumulative basis, impacts to sensitive receptors could be cumulatively considerable where more than one source emitter occurs in proximity to a sensitive receptor. Even when the individual sources are within regulatory limits, the potential exists for limits to be exceeded on a cumulative basis. This is particularly true for incremental mobile source (vehicular) emissions from major freeways with existing or future high traffic volumes.

- Further, as the exact location, timing and level of future development activities arising from build out of any of the General Plan scenarios cannot be foreseen to the degree of specificity necessary, specific impacts to sensitive receptors cannot be quantified. Thus, even after complying with regulations and implementing all mitigation measures, impacts cannot be guaranteed to be reduced to below applicable agency thresholds. Thus, this impact is considered cumulatively significant and unavoidable with respect to exposure of sensitive receptors for any of the General Plan build out scenarios, including that encompassing the project (i.e., GPU/GPA960).

- Due to the programmatic nature of the project, detailed construction phasing, equipment and intensities cannot be foreseen with reasonable accuracy at this time. Because of the increased density seen for the land uses and desired proximity of residential land uses to both transit and commercial centers, it can be assumed that both construction and operation of commercial and potentially industrial sources would be developed relatively close to sensitive receptors such as residences or schools. Thus, effects of project emissions on sensitive receptors throughout Riverside County must be considered significant and unavoidable.

- Localized emissions of toxic air contaminants (TAC) are of concern with respect to sensitive receptors. The primary source of TACs within the County of Riverside is vehicles, particularly diesel-fueled trucks, using the freeways and major roadways throughout the county. Buffer zones can help insulate sensitive receptors from TAC sources. However, residual incremental impacts must be assumed to be cumulatively considerable and unavoidable in the absence of site-specific proof of adequate mitigation.

(2) Non-Substantial Incremental Impacts

- Although almost any land use has the potential to emit odors, some land uses, such as chemical plants, composting operations, dairies, certain agricultural activities, landfills, etc., are more likely to produce odors because of their operations. For such uses, however, setbacks or buffers, and other site-specific and industry-specific measures are typically required to control odors. Although incremental odor emissions would result, such uses are not typically allowed to be developed in concentrations that would yield cumulatively considerable impacts.

- Construction activities associated with project implementation would generate airborne odors as a result of operation of construction vehicles (i.e., diesel exhaust), paving with hot asphalt and the application of architectural coatings. Because of the volatile nature of odor compounds, they either react quickly in the atmosphere or are diluted as they are carried away from the odor source. Therefore, construction odors are generally isolated and limited to the duration of construction and its immediate site vicinity. As such, they would not affect a substantial number of people as impacts related to these odors are limited to the number of people living and working nearby the source. Further, while some components of asphalt and diesel emissions are considered toxic air contaminants, construction activities do not generally cause significant odor impacts because of the duration of exposure. Future build out of any of the various General Plan scenarios, including that encompassing the project (GPU/GPA960) would not have cumulatively significant impacts due to odors.

d. Mitigation

As described in detail in Section 4.6.3, a variety of measures would be implemented to avoid, reduce and minimize adverse cumulative air quality impacts. These include the following:

(1) Regulatory Compliance

Key Regulations and Program: See Section 4.6.3 for the text of each policy.

- SCAG 2007 Air Quality Management Plan

- SCAQMD Attainment Plans

- MDAQMD Attainment Plans
- SCAQMD Rules addressing odors: e.g., Rule 402 (Nuisances), Rule 410 (Odors), Rule 1179 (Treatment Works)
- Ordinance No. 659 - Residential Development Impact Fee Program
- Ordinance No. 706 - Mobile Source Air Pollution Reduction Programs Funding
- Ordinance No. 726 - Transportation Demand Management for New Development
- Ordinance No. 748 - Mitigation of Traffic Congestion Through Signalization
- Ordinance No. 782 - Golf Cart Transportation Plan
- Ordinance No. 824 - Western Riverside County Traffic Uniform Mitigation Fee Program

Key General Plan Policies: See Section 4.6.3 for the text of each policy.

- Air Quality Element Policies: AQ 1.1-1.11, 2.1-2.4, 3.1-3.4, 4.1-4.10, 5.1-5.4, 7.1-7.4, 8.2, 8.4, 8.6-8.9, 9.1, 9.2, 10.1-10.4, 11.3, 11.4, 13.1-13.3, 14.1, 14.2, 14.4, 15.1, 16.1-16.4, 17.1-17.11, 19.1, 20.1, 22.1, 23.1, 24.1, 25.1, 26.1, 26.2, 27.1, 28.1 and 29.1-29.3
- Circulation Element Policies: C 1.2, 1.7, 4.1, 4.8, 9.2, 11.2, 11.4-11.7, 12.1-12.3, 13.1-13.3, 17.3, 17.4, 20.14 and 21.1
- Land Use Element Policies: LU 1.5, 2.1, 4.1, 8.12, 11.1-11.4 and 13.1-13.4
- Open Space Element Policies: OS 12.1 and 16.1-16.8

(2) CEQA Mitigation

Existing Mitigation Measures: In EIR No. 441, prepared for the 2003 RCIP General Plan, mitigation was imposed to reduce impacts to air quality. These measures remain applicable to this project (GPA No. 960) and would lessen impacts to air quality.

- **Existing MM 4.5.1A:** Applicable Rule 403 Measures: Apply nontoxic chemical soil stabilizers according to manufacturers' specifications to all inactive construction areas (previously graded areas inactive for ten days or more).

  a. Water active sites at least twice daily. (Locations where grading is to occur will be thoroughly watered prior to earthmoving).

  b. All trucks hauling dirt, sand, soil, or other loose materials are to be covered, or should maintain at least two feet of freeboard in accordance with the requirements of California Vehicle Code (CVC) section Section 23114 (freeboard means vertical space between the top of the load and top of the trailer).

  c. Pave construction access roads at least 100 feet onto the site from main road.

d. Traffic speeds on all unpaved roads shall be reduced to 15 mph or less.

- **Existing MM 4.5.1B:** [Implement the following] additional SCAQMD CEQA Air Quality Handbook dust measures:

  a. Revegetate disturbed areas as quickly as possible.

  b. All excavating and grading operations shall be suspended when wind speeds (as instantaneous gusts) exceed 25 mph.

  c. All streets shall be swept once a day if visible soil materials are carried to adjacent streets (recommend water sweepers with reclaimed water).

  d. Install wheel washers where vehicles enter and exit unpaved roads onto paved roads, or wash trucks and any equipment leaving the site each trip.

- **Existing MM 4.5.1C**: [Implement the following] mitigation measures for construction equipment and vehicles exhaust emissions:

  a. The construction contractor shall select the construction equipment used on site based on low emission factors and high energy efficiency.

  b. The construction contractor shall ensure that construction grading plans include a statement that all construction equipment will be tuned and maintained in accordance with the manufacturer's specifications.

  c. The construction contractor shall utilize electric- or diesel-powered equipment, in lieu of gasoline-powered engines, where feasible.

  d. The construction contractor shall ensure that construction grading plans include a statement that work crews will shut off equipment when not in use. During smog season (May through October), the overall length of the construction period will be extended, thereby decreasing the size of the area prepared each day, to minimize vehicles and equipment operating at the same time.

  e. The construction contractor shall time the construction activities so as to not interfere with peak hour traffic and minimize obstruction of through traffic lanes adjacent to the site; if necessary, a flagperson shall be retained to maintain safety adjacent to existing roadways.

  f. The construction contractor shall support and encourage ridesharing and transit incentives for the construction crew.

  g. Dust generated by the development activities shall be retained on site and kept to a minimum by following the dust control measures listed below.

     i. During clearing, grading, earthmoving, excavation, or transportation of cut or fill materials, water trucks or sprinkler systems shall be used to prevent dust from leaving the site and to create a crust after each day's activities cease.

ii. During construction, water trucks or sprinkler systems shall be used to keep all areas of vehicle movement damp enough to prevent dust from leaving the site. At a minimum, this would include wetting down such areas in the late morning, after work is completed for the day and whenever wind exceeds 15 miles per hour.

iii. Immediately after clearing, grading, earthmoving, or excavation is completed, the entire area of disturbed soil shall be treated until the area is paved or otherwise developed so that dust generation will not occur.

iv. Soil stockpiled for more than two days shall be covered, kept moist, or treated with soil binders to prevent dust generation.

v. Trucks transporting soil, sand, cut or fill materials and/or construction debris to or from the site shall be tarped from the point of origin.

New Mitigation Measures: The following additional project-specific mitigation measures would be necessary to ensure that air quality impacts are avoided, reduced or minimized to the extent feasible. Implementation of these additional mitigation measures would help reduce project impacts, although it would not be guaranteed that the impacts would be cumulatively reduced to below threshold levels (even if individual emission reductions to adequate levels were achieved). See Section 4.6.6 for more details. Note, MMs numbered in the 4.7 series are greenhouse gas reduction measures proposed in Section 4.7.6 that will also help reduce criteria pollutant emissions.

- **New MM 4.6.B-N1:** The construction contractor shall ensure that all disturbed areas and stock piles are watered at least three times per day or soil stabilizers are applied as necessary to prevent visible dust plumes from these areas. Stock piles not in use may be covered with a tarp to eliminate the need for watering or other stabilizers.

- **New MM 4.6.B-N2:** All construction equipment shall have EPA rated engines of Tier 3 or better.

- **New MM 4.6.B-N3:** As soon as electric utilities are available at construction sites, the construction site shall be supplied with electricity from the local utility and all equipment that can be electrically operated shall use the electric utility rather than portable generators.

- **New MM 4.6.B-N4:** All new development shall ensure that all interior and exterior architectural coatings used are low in reactive organic gases.

- **New MM 4.6.B-N5:** If hearths are included in new residential developments, they shall be energy-efficient natural gas appliances. No wood-burning hearths or stoves shall be permitted in new residential developments.

- **New MM 4.6.D-N1:** New developments shall include the following requirements to reduce emissions associated with toxic air contaminants (TACs):

  a. Electrical outlets shall be included in the building design of any loading docks to allow use by refrigerated delivery trucks. Signage shall also be installed, instructing commercial vehicles to limit idling times to five minutes or less. If loading and/or unloading of perishable goods would occur for more than five minutes and continual refrigeration is required, all refrigerated delivery trucks shall use

the electrical outlets to continue powering the truck refrigeration units when the delivery truck engine is turned off.

b. Electrical outlets shall be installed on the exterior of new structures for use with electrical landscaping equipment. Further, the property owner(s) shall ensure that the hired landscape companies use electric powered equipment where available to a minimum of 20% of the equipment used.

- **New MM 4.6.D-N2:** The County of Riverside shall require minimum distances between potentially incompatible land uses, as described below, unless a project-specific evaluation of human health risks defines, quantifies and reduces the potential incremental health risks through site design or the implementation of additional reduction measures to levels below applicable standards (e.g., standards recommended or required by CARB, SCAQMD or MDAQMD).

  SCAQMD Jurisdiction:

  a. Proposed dry cleaners and film processing services that use perchloroethylene must be sited at least 500 feet from existing sensitive land uses including residential, schools, day care facilities, congregate care facilities, hospitals or other places of long-term residency for people.

  b. Proposed auto body repair services shall be sited at least 500 feet from existing sensitive land uses.

  c. Proposed gasoline dispensing stations with an annual throughout throughput of less than 3.6 million gallons shall be sited at least 50 feet from existing sensitive land uses. Proposed gasoline dispensing stations with an annual throughput at or above 3.6 million gallons shall be sited at least 300 feet from existing sensitive land uses.

  d. Other proposed sources of TACs including furniture manufacturing and repair services that use methylene chloride or other solvents identified as a TAC shall be sited at least 300 feet from existing sensitive land uses.

  e. Proposed sensitive land uses shall be sited at least 500 feet from existing freeways, major urban roadways with 100,000 vehicles per day or more and major rural roadways with 50,000 vehicles per day or more.

  f. Proposed sensitive land uses shall be sited at least 500 feet from existing dry cleaners and film processing services that use perchloroethylene.

  g. Proposed sensitive land uses shall be sited at least 500 feet from existing auto body repair services.

  h. Proposed sensitive land uses shall be sited at least 50 feet from existing gasoline dispensing stations with an annual throughput of less than 3.6 million gallons and 300 feet from existing gasoline dispensing stations with an annual throughput at or above 3.6 million gallons.

  i. Proposed sensitive land uses shall be sited at least 300 feet from existing land uses that use methylene chloride or other solvents identified as a TAC.

  MDAQMD Jurisdiction:

  a. Proposed industrial projects must be sited at least 1,000 feet from existing sensitive land uses.

b. Proposed distribution centers with 40 or more trucks per day shall be sited at least 1,000 feet from existing sensitive land uses.

c. Proposed dry cleaner using perchloroethylene shall be sited at least 500 feet from existing sensitive land uses.

d. Proposed gasoline dispensing facility shall be sited at least 300 feet from existing sensitive land uses.

e. Proposed sensitive land uses shall be sited at least 500 feet from existing freeways, major urban roadways with 100,000 vehicles per day or more and major rural roadways with 50,000 vehicles per day or more.

f. Proposed sensitive land uses shall be sited at least 1,000 feet from existing industrial facilities or distribution centers with more than 40 trucks per day.

g. Proposed sensitive land uses shall be sited at least 500 feet from existing dry cleaners using perchloroethylene.

h. Proposed sensitive land uses shall be sited at least 300 feet from existing gasoline dispensing stations.

- **New MM 4.6.E-N1:** Locate potential new odor sources predominantly down- or crosswind from existing sensitive receptors and potential new sensitive receptors predominantly upwind from existing odor sources. As indicated by the "Right-to-Farm" ordinance, agricultural uses that have been operated for more than three years cannot be re-classified as a public or private nuisance by new development.

- **New MM 4.6.E-N2:** Maintain an adequate buffer between potential new odor sources and receptors such that emitted odors are dissipated before reaching the receptors (minimum of 500 feet depending on odor source). As indicated by the "right-to-farm" ordinance, agricultural uses that have been operated for more than three years cannot be re-classified as a public or private nuisance by new development.

- **New MM 4.6.E-N3:** Design odor-emitting facilities such that odor emitters are located as far from potential receptors as possible. Also, balance stack heights to provide the maximum dispersion of odor between the stack and the nearest sensitive receptor.

- **New MM 4.7.A-N1:** To ensure GHG emissions resulting from new development are reduced to levels necessary to meet State of California targets, the County of Riverside shall require all new discretionary development to comply with the Implementation Measures of the Riverside County Climate Action Plan or provide comparable custom measure backed by a project GHG study (for example, using CalEEMod modeling) demonstrating achievement of the same target. The target to be met is a GHG emissions reduction of 25% below emissions for the adjusted BAU scenario for residential, commercial, industrial, institutional and mixed-use projects. The adjusted BAU is based upon the 2020 BAU found in the Final Supplement to the AB 32 Scoping Plan (CARB 2011).

- **New MM 4.7.A-N2:** In lieu of a project-specific GHG analysis per Mitigation Measure 4.7.A-N1, a future discretionary project pursuant to the Riverside County General Plan shall incorporate into the project design, operational features and/or Implementing Measures from the Riverside County Climate Action Plan, in such a manner as to garnish at least 100 points. The point values within the CAP's Screening Tables constitute GHG emission reductions.

- ***New Mitigation Measure 4.7.A-N3:*** *The County of Riverside will monitor implementation of the reduction measures and revise or amend the Climate Action Plan as needed based upon the results of monitoring to ensure achievement of the 2020 Reduction Target. In addition, the County of Riverside will start update process of the Climate Action Plan in 2017 to provide a post-2020 plan. The post-2020 Climate Action Plan update will include a specific target for GHG reductions for 2035 and 2050. The targets will be consistent with broader state and federal reduction targets including Executive Order S-3-05 and with the scientific understanding of the needed reductions by 2050. The post-2020 Climate Action Plan update will include a set of updated reduction measures to achieve the 2035 and 2050 Reduction Targets and updated monitoring system to ensure that the updated targets are achieved. The County of Riverside will adopt the new post-2020 Climate Action Plan update by January 1, 2020.*

e. Significance

The analysis presented above indicates that future development consistent with the proposed project, GPA No. 960, would contribute less than significant incremental impacts with respect to odors. For all other air quality impacts, however, incremental contributions will be cumulatively considerable, even with implementation of all feasible mitigation. Incremental contributions of future development, including that accommodated by GPA No. 960, would result in cumulatively considerable impacts due to construction and operational emissions of criteria pollutants, associated violations of air quality standards or thresholds, and effects to sensitive receptors, both locally and regionally. Even where individual future development projects were successfully mitigated to less than significant levels, they would still contribute incrementally to cumulatively significant air quality impacts. Because there is no feasible mechanism for the County of Riverside to control individual projects with respect to their incremental pollutant contributions, impacts to air quality would remain significant and unavoidable.

6. Cumulative Effects on Greenhouse Gas Emissions

Section 4.7 (Greenhouse Gases) of this EIR discusses specifics regarding existing and future greenhouse gas emissions in Riverside County. It also analyzes the impacts from future development accommodated by the changes proposed by the project, GPA No. 960, as well as the regulations, policies and mitigation measures that would *help reduce (but not entirely avoid) significant* ~~ensure~~ impacts~~ are less than significant~~. To avoid repetition, information already covered in Section 4.7 is not repeated here. Refer back to Section 4.7 directly for additional details on greenhouse gases, particularly background information on global climate change.

Section 4.7 provides a complete description of the carbon inventory of Riverside County, as well as analysis of existing and future greenhouse gas (GHG) impacts projected to occur as Riverside County builds out. This data includes Table 4.7-A (Existing Riverside County Landfills), Table 4.7-B (Closed Riverside County Landfills), Table 4.7-C (2008 Net Total GHG Emissions for Unincorporated Riverside County), Table 4.7-D (Construction GHG Emissions – Residential Examples), Table 4.7-E (2020 BAU [Business As Usual] Operational GHG Emissions Inventory), Table 4.7-F (2020 Reduced GHG Emissions Inventory), Table 4.7-G (2020 Operational GHG Emissions – Scenario Comparisons), Table *4.7-I* ~~4.7-H~~ (2020 Operational GHG Emissions – Scenario Comparisons) and Table *4.7-H* ~~4.7-I~~ (SB 375 Target Comparisons). It also includes three pie charts: Figure 4.7.1 (2008 Greenhouse Gas Emissions in Unincorporated Riverside County), Figure 4.7.2 (2020 BAU Greenhouse Gas Emissions) and Figure 4.7.3 (2020 Reduced Scenario – Operational Greenhouse Gas Emissions)*, as well as a line graph, Figure 4.7.4 (Riverside County GHG Emissions with Reductions in CAP and Post-2020 CAP)*.

a. Existing Conditions

Greenhouse gases (GHGs) trap heat in the atmosphere, which in turn heats the surface of the Earth. Some GHGs occur naturally and are emitted to the atmosphere through natural processes, while others are created and

emitted solely through human activities, primarily through the combustion of fossil fuels. In the last decade, the State of California has recognized that anthropogenic (human-caused) greenhouse gas emissions are contributing to changes in the global climate and that such changes have adverse effects on the environment, the economy and public health. These are cumulative effects of past, present and future actions worldwide. While the worldwide contributions of GHG emissions are expected to have widespread consequences, it is not possible to link particular changes to the environment of California or elsewhere to GHG emitted from a particular source or location. Thus, this EIR only examines GHG emissions at the regional (countywide) and local (future implementing projects) levels.

Direct emissions are those emitted directly from a project's onsite sources, such as gas-powered equipment (e.g., lawnmowers, etc.), backyard grills, etc., as well as mobile (vehicular) sources associated with travel. Indirect emissions are associated with off-site GHG generation, such as production of electricity or pumping imported water across the state. Impacts from GHG emissions are inherently cumulative: unlike criteria pollutants, they do not cause "local" effects. They only cause effects at the global level (climate change) as a result of many millions of sources and contributing actions worldwide. Thus, in large part the analyses presented in Section 4.7 can already be said to represent "cumulative" effects. Presented herein, however, is the additional "cumulative GPAs" General Plan build out scenario not already covered in Section 4.7.

California law defines GHGs to include the following compounds: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs) and sulfur hexafluoride (SF_6) (State CEQA Guidelines, Section 15364.5 and Health and Safety Code, Section 38505(g)). The most common GHG that results from human activity is carbon dioxide, followed by methane and nitrous oxide. Chlorofluorocarbons (CFCs), primarily used as refrigerants, aerosol propellants and cleaning solvents, are banned in California and Riverside County does not have any significant CFC emissions. Other synthesized gases, such as hydrofluorocarbons (HFCs) and carbon tetrafluoride (CF_4), have also been banned and are no longer available on the market. Thus, Riverside County does not have any significant sources of these GHGs either. Another GHG with a high GWP, SF_6 is mainly used in the electric switchgear of high voltage electric transmission lines and medical use in retinal detachment surgery and ultrasound imaging. These are the only two uses of SF_6 reported in Riverside County and are not used in cumulatively significant levels.

Section 4.7.2 includes the specifics on the baseline GHG emissions data that was developed for unincorporated Riverside County and the County of Riverside government operations. Note that the GHG emissions herein encompass only those from emission sources within unincorporated Riverside County or from activities that the County of Riverside has direct or indirect jurisdictional control (for example, county buildings located in a city). The GHG emissions inventories identify major sources and quantities of GHG emissions produced by Riverside County residents, businesses and government (County of Riverside) operations. Using historic emissions and business-as-usual (BAU) practices as the basis, the inventories include GHG emissions from 2008 (baseline) and projected for 2020 and beyond. The year 2008 was used as the baseline to inventory emissions for existing conditions as it was the most recent year with complete data. The methodology and data sources used to estimate the various types of existing (*as of* 2008) GHG emissions are described in Section 4.7.2 and the 2035 results of modeled estimates for, including both BAU and reduced scenarios, are described in Section 4.7.4 *for base (2008), intermin (2020, 2035) and buildout (2050-2060) years*.

In terms of land use, GHG emissions are predicted based on the types of activities associated with the given use and may span a number of sectors. For example, a single-family home would be associated with GHG emissions from transportation (commuting to work, say), waste generation (trash and lawn clippings) and energy consumption (electricity to run appliances and lights, natural gas to heat the house and cook, etc.). Accordingly, GHG inventories include emissions from the following categories: electricity, natural gas, solid waste, area sources, water-related emissions, agriculture and transportation. See Section 4.7.2 for more information.

b. Future Conditions

The GHG inventories for a variety of existing and future conditions are presented below. The data used below comes from Section 4.7 plus an addendum document issued by Atkins entitled: Technical Summary Report of Changes to Air Quality and Greenhouse Gas (GHG) Emissions from Cumulative Traffic Associated with the [Cumulative] General Plan Amendments *and GHG Emission Sources Attributiable to County Landfill Operations*, dated *December 31, 2014* ~~July 18, 2013~~ (see Appendix EIR-10). The addendum includes analyses of GHG emissions associated with the CULM General Plan build out scenario.

Consistent with Section 4.7, the Atkins addendum indicates that without mitigation, build out of the General Plan with the project (GPU/GPA 960) would be cumulatively considerable with respect to GHG emissions and AB 32 targets for 2020. However, with the mitigation provided in the General Plan, proposed Riverside County Climate Action Plan (CAP) and the EIR (i.e., the "2020 Reduced" column in Table 5.5-K), project and GPU/GPA 960 GHG emissions would be cumulatively non-substantial. The same pattern holds for the project, the GPU/GPA 960 build out, and per-capita emissions *for 2035* relative to SB 375 (see Table 5.5-L).

Beyond 2035, however, the ability to ensure adequate mitigation for GHGs becomes tenuous at best. Specifically, GHG emissions occurring within Riverside County between 2020 and 2060 would be cumulatively significant and unavoidable because they would contribute to GHG levels in excess of the 2050 mitigation targets established for California under Executive Order S-3-05, i.e., reducing GHG emissions to "80% below 1990 levels by 2050." The County is committed toward the reduction of GHG emissions. However, the means to achieve the 2050 reduction target is technologically infeasible at this time. Mitigation Measure 4.7.A-.N3 requires the County to provide by January 1, 2020, a post-2020 CAP that includes 2035 and 2050 reduction targets and specific reduction measures to achieve those targets. This allows technology, the State and the County the time needed to develop reduction measures able to achieve the 2050 reduction target. At present, however, there is no feasible mitigation to fully reduce this cumulative impact to below the level of significance in terms of 2050 targets. Thus, even though project effects may be individually limited, GPA No. 960's incremental contribution to these cumulative greenhouse gas impacts would be significant and unavoidable. See Section 5.5.C.6 for full analysis and details.

When examining the CULM scenario, ~~however,~~ Atkins finds that "there would be a marked increase in mobile source GHG emissions in both the business as usual (BAU) and reduced operational emissions conditions" due to the increased vehicle trips (VMT, vehicle miles traveled). Unlike the project and the GPU/GPA 960 scenario, however, the CULM scenario's incremental GHG emissions at build out would be cumulatively considerable even with mitigation *for years 2020 and 2035. Both scenarios (GPU and CULM) would be cumulatively considerable for GHG impacts beyond 2035 to 2060 based on present technology and mitigation feasibility.* As shown in Tables 5.5-K and 5.5-L, for the CULM scenario, the Atkins addendum concludes that impacts would be cumulatively significant and unavoidable because the reduction target could not be met. See addendum for full details on the assumptions, calculations and modeling results used.

c. Impacts

As discussed in greater detail in Section 4.7, future development accommodated by the project will contribute incrementally to cumulative greenhouse gas emissions as Riverside County builds out over time pursuant to the various General Plan scenarios. Specific impacts will include the following:

- **Generation of Greenhouse Gas Emissions:** Build out of Riverside County over time pursuant to any of the General Plan scenarios, including GPU/GPA 960, which encompasses the proposed project (GPA 960), would result in future construction and operational activities that generate GHGs. Either individually or collectively, these activities can result in substantial emissions of GHGs; for example, exceeding the 3,000-10,000 metric tons per year (MTY) thresholds proposed by the SCAQMD in Tier 3

of its 2008 Interim CEQA Greenhouse Gas Significance Thresholds. For all but the CULM scenario, however, implementation of the proposed General Plan policies and particularly, the Implementation Measures in the proposed CAP, plus a variety of proposed mitigation measures, would be sufficient to ensure that incremental GHG emissions in Riverside County are less than significant *through at least 2020 to 2035, based on available technology and feasibility of current mitigation.*

Table 5.5-K: Cumulative Operational Greenhouse Gas Emissions (AB 32)

Scenarios & Net GHG Emission Sources[1]	Net GHG Emissions (Metric Tons of CO_2e)

Significant? [3]	***YES***	***YES***	***YES***

Footnotes:
1. All values (except thresholds) rounded to nearest 10. Thus, totals may not sum precisely. See Appendix EIR-10 for data. No data available for existing General Plan build out (CURR GP scenario).
2. All scenarios use the same data for 2008 since they all start from the same unmitigated baseline conditions. It should be noted that the "yes" results for the build out scenarios reflect the fact that even if no General Plan Amendments were approved, Riverside County would still have significant GHG emissions if unmitigated.
3. Significant ("yes") if target exceeded. For source of AB 32 targets, see Table 4.7-C.

Footnotes:
1. All values (except per-capita) rounded to nearest 10. Thus, totals may not sum precisely. See Appendix EIR-~~10~~ 6 for data. No data available for existing General Plan build out (CURR GP scenario).
2. All scenarios use the same data for 2008 since they all start from the same unmitigated baseline conditions. It should be noted that the "yes" results for the build out scenarios reflect the fact that even if no General Plan Amendments were approved, Riverside County would still have significant GHG emissions if unmitigated.
3. Automobiles and light-duty trucks.
4. Significant ("yes") if target exceeded. For SB 375 targets, see Table 4.7-H.

Source: Atkins, Letter Addendum, *December 2014* ~~July 2013~~, Table GHG-2. See Appendix EIR-10.

- **Construction GHG Emissions:** Construction activities will result in GHG emissions from individual public and private projects implemented pursuant to General Plan build out. The exact amount of emissions would be dependent on the particular construction equipment used, length of construction and the number of projects occurring at any given time. Following SCAQMD methodology, construction emissions are amortized into a project's GHG emissions total, which must then be mitigated as outlined in the draft CAP. The results in Table 5.5-K indicate that with the implementation of the items outlined for the "2020 Reduced" scenarios (i.e., emission results after imposition of regulatory and mitigation measures), incremental GHG emissions associated with the GPU/GPA 960 (i.e., with project) build out scenario in Riverside County will be cumulatively less than significant.

- **Operational GHG Emissions:** To comply with state laws (AB 32), cumulative GHG emissions for Riverside County need to be at or below the 1990 emission levels by the year 2020. Using this threshold, the regulatory and mitigation measures outlined below (and, in particular, from the ~~draft~~ CAP) would ensure that cumulative GHG emissions in Riverside County are consistent with this target *for 2020*. As indicated in Table 5.5-K, incremental GHG emissions associated with the GPU/GPA 960 (project) build out scenario will be cumulatively less than significant *for at least AB 32's 2020 target*.

- **Conflict with GHG Reduction Plans, Policies or Regulations:** Implementation of the General Plan, as updated pursuant to the proposed project (i.e., the GPU/GPA 960 scenario), would result in future construction and operational activities that generate GHGs. This generation of GHGs would potentially conflict with the implementation of AB 32 and SB 375, California policies for reducing GHG emissions. However, implementation of the proposed General Plan policies and particularly the Implementation Measures of the Riverside County CAP, plus proposed new Mitigation Measures 4.7.A-N1 and 4.7.A-N2, would ensure that build out of the General Plan, as amended by GPA No. 960, would be consistent with both Riverside County's proposed Climate Action Plan (CAP) and State of California mandates (under AB 32 and SB 375), *at least as applies to years 2020 and 2035, and* ~~as well as~~ have a less than significant impact on their implementation *for this interim period. For long-range GHG reduction targets, however, both project (GPU) and CULM scenarios would result in cumulatively significant impacts. In particular, GHG emissions occurring within Riverside County between 2020 and 2060 would be cumulatively significant and unavoidable because they would contribute to GHG levels in excess of the 2050 mitigation targets established for California under Executive Order S-3-05, i.e., reducing GHG emissions to "80% below 1990 levels by 2050." The County is committed toward the reduction of GHG emissions. However, the means to achieve the 2050 reduction target is technologically infeasible at this time. New Mitigation Measure 4.7.A-N3 requires the County to provide by January 1, 2020, a post-2020 CAP that includes 2035 and 2050 reduction targets and specific reduction measures to achieve those targets. This allows technology, the State and the County the time needed to develop reduction measures able to achieve the 2050 reduction target. At present, however, there is no feasible mitigation to fully reduce this cumulative impact to below the level of significance in terms of 2050 targets.*

Thus, even though project effects may be individually limited, GPA No. 960's incremental contribution to these cumulative greenhouse gas impacts would be significant and unavoidable.

- **Consistency with AB 32 and SB 375:** Per Tables 5.5-K and 5.5-L, with mitigation, in particular the CAP Implementation Measures (as discussed under Impact 4.7.1 in Section 4.7), Riverside County's cumulative 2020 GHG emissions would meet regulatory targets for both AB 32 and SB 375 for the GPU/GPA 960 (i.e., with project) build out scenario *through at least 2020 to 2035. As discussed above, it is at present technologically infeasible to ensure full mitigation to less-than-significant levels (i.e., 90% of 1990 levels) for GHG emissions beyond 2035 to buildout (2050-2060). This applies to both the project (GPU/GPA 960) and CULM build-out (2060) scenarios.* Thus, the incremental contributions associated with GPA No. 960 would *only* be cumulatively less than significant *through 2020-2035*. For the CULM scenario, *data for the 2020, 2035 and buildout periods* ~~however, the same tables~~ indicate that even with mitigation, impacts would be cumulatively considerable and further reduction measures *not presently technolocially feasible,* ~~related to electric vehicles, for example,~~ would be necessary. See the Atkins addendum for more information.

d. Mitigation

As described in detail in the applicable subsections of 4.7.5, a variety of measures would be implemented to avoid, reduce and minimize adverse cumulative impacts from GHG emissions and ensure regulatory compliance. These include the following items:

(1) Regulatory Compliance

Key Regulations and Program: See Section 4.7.3 for information on each regulation.

- California Executive Order S-3-05 - Establishing GHG Emission Reduction Targets
- California Executive Order S-13-08 - Establishing Climate Adaption Strategies
- California Assembly Bill 32 - Global Warming Solutions Act of 2006
- California Senate Bill 375 - Sustainable Communities and Climate Protection Act
- California Ambient Air Quality Standards
- CCR Title 24, Part 6 - Energy Efficiency Standards
- Ordinance No. 559 - Regulating the Removal of Trees
- Ordinance No. 655 - Regulating Light Pollution
- Ordinance No. 659 - Residential Development Impact Fee (DIF) Program
- Ordinance No. 695 - Requiring the Abatement of Hazardous Vegetation
- Ordinance No. 706 - Mobile Source Air Pollution Reduction Programs (Funding)
- Ordinance No. 726 - Transportation Demand Management for New Development

- Ordinance No. 748 - Mitigation of Traffic Congestion through Signalization
- Ordinance No. 782 - Golf Cart Transportation Plan
- Ordinance No. 810 - Establishing an Interim Open Space Mitigation Fee
- Ordinance No. 824 - Western Riverside County Traffic Uniform Mitigation Fee (TUMF) Program
- Ordinance No. 859 - Establishing Water-Efficient Landscaping Standards
- Ordinance No. 875 - Establishing Mitigation Fees for Coachella Valley Multi-Species Habitat Conservation Plan
- Board of Supervisors Policy No. A-64 - Environmental Purchasing
- Board of Supervisors Policy No. H-4 - Energy Conservation
- Board of Supervisors Policy No. H-25 - Water Efficient Landscaping
- Board of Supervisors Policy No. H-29 - Sustainable Building

Key General Plan Policies: See Section 4.7.3.E and F. for the text of each policy.

- Air Quality Element Policies: AQ 1.1-1.4, 1.7, 3.2, 3.4, 4.4, 5.1, 5.2, 5.4, 8.4-8.9, 10.1-10.4, 13.1, 21.1-21.5, 22.1, 23.1, 23.2, 24.1, 24.2, 25.1-25.3, 26.1, 26.2, 27.1, 27.2, 28.1, 28.2, 29.1-29.4 and 30.1-30.5
- Circulation Element Policies: C 1.2, 1.7, 4.1, 4.8, 5.2, 9.2, 11.2, 11.4, 11.5, 11.7, 12.1, 12.2, 13.1-13.3, 17.3, 17.4, 21.1 and 21.9
- Land Use Element Policies: LU 1.5, 2.1, 4.1, 8.12, 11.1, 11.3, 11.4 and 13.1-13.4
- Open Space Element Policies: OS 2.2, 2.5, 10.1, 11.1-11.3, 12.1 and 16.3-16.8

(2) CEQA Mitigation

Existing Mitigation Measures: In EIR No. 441, prepared for the 2003 RCIP General Plan, mitigation was imposed to reduce air quality pollutants. Since GHG emissions are also produced from some of the same sources (particularly vehicular exhaust), these measures are also applicable to this project (GPA No. 960) and would lessen impacts from GHG emissions as well.

- **Existing MM 4.5.1C:** Mitigation measures for construction equipment and vehicles exhaust emissions:

  a. The construction contractor shall select the construction equipment used on site based on low emission factors and high energy efficiency.

  b. The construction contractor shall ensure that construction grading plans include a statement that all construction equipment will be tuned and maintained in accordance with the manufacturer's specifications.

c. The construction contractor shall utilize electric- or diesel-powered equipment, in lieu of gasoline-powered engines, where feasible.

d. The construction contractor shall ensure that construction grading plans include a statement that work crews will shut off equipment when not in use. During smog season (May through October), the overall length of the construction period will be extended, thereby decreasing the size of the area prepared each day, to minimize vehicles and equipment operating at the same time.

e. The construction contractor shall time the construction activities so as to not interfere with peak hour traffic and minimize obstruction of through traffic lanes adjacent to the site; if necessary, a flag person shall be retained to maintain safety adjacent to existing roadways.

f. The construction contractor shall support and encourage ridesharing and transit incentives for the construction crew.

g. [Item g, dust control measures omitted, since not applicable to GHGs].

New Mitigation Measures: The following additional project-specific mitigation measures would be necessary to ensure that GHG impacts are avoided, reduced or minimized to below threshold levels. See Section 4.7.6 for additional details.

- **New MM 4.7.A-N1:** To ensure GHG emissions resulting from new development are reduced to levels necessary to meet State targets, the County of Riverside shall require all new discretionary development to comply with the Implementation Measures of the Riverside County Climate Action Plan or provide comparable custom measures backed by a project GHG study (for example, using CalEEMod modeling) demonstrating achievement of the same target. The target to be met is a GHG emissions reduction of 25% below emissions for the adjusted BAU scenario for residential, commercial, industrial, institutional and mixed-use projects. The adjusted BAU is based upon the 2020 adjusted BAU found in the Final Supplement to the AB 32 Scoping Plan (CARB 2011).

- **New MM 4.7.A-N2:** In lieu of a project-specific analysis per Mitigation Measure 4.7.A-N1, a future discretionary project proposed pursuant to the Riverside County General Plan shall incorporate into the project design, operational features and/or Implementing Measures from the Riverside County Climate Action Plan, in such a manner as to garnish at least 100 points. The point values within the CAP's Screening Tables constitute GHG emission reductions.

- ***New MM 4.7.A-N3:*** *The County of Riverside will monitor implementation of the reduction measures and revise or amend the Climate Action Plan as needed based upon the results of monitoring to ensure achievement of the 2020 Reduction Target. In addition, the County of Riverside will start update process of the Climate Action Plan in 2017 to provide a post-2020 plan. The post-2020 Climate Action Plan update will include a specific target for GHG reductions for 2035 and 2050. The targets will be consistent with broader state and federal reduction targets including Executive Order S-3-05 and with the scientific understanding of the needed reductions by 2050. The post-2020 Climate Action Plan update will include a set of updated reduction measures to achieve the 2035 and 2050 Reduction Targets and updated monitoring system to ensure that the updated targets are achieved. The County of Riverside will adopt the new post-2020 Climate Action Plan update by January 1, 2020.*

e. Significance

Implementation of, and compliance with, the above regulations, policies and mitigation measures would ensure that incremental impacts due to greenhouse gas emissions from future development within Riverside County are minimized to a level that is cumulatively less than significant, including GHG emissions from construction and operational activities. Following the 2020 emissions analysis, it was determined that future development authorized pursuant to the General Plan, as amended by the proposed project (i.e., the GPU/GPA 960 scenario), would not conflict with the implementation of AB 32. Through an analysis of passenger vehicle emissions for 2020 and 2035, it was also determined that the updated General Plan would be consistent with the targets for the SCAG region under SB 375 with mitigation. Compliance with existing and proposed General Plan policies and, in particular, the County Climate Action Plan's implementing measures and screening tables, plus the mitigation measures herein, would ensure that any future development activities approved within Riverside County reduce greenhouse gas emissions, fully mitigate or avoid any GHG impacts and are consistent with the State of California and County of Riverside's greenhouse gas reduction polices and the Climate Action Plan.

7. Cumulative Effects on Biological Resources

Section 4.8 (Biological Resources) discusses existing biological resources within Riverside County, as well as the sources used (and any updates made to them) for this data. The section also analyzes biological impacts from future development accommodated by the changes proposed by the project, GPA No. 960, as well as the mitigation (both through regulatory compliance and CEQA-specific mitigation) necessary to ensure impacts are less than significant. As a result, areas already covered in Section 4.8 are not repeated here. See Section 4.8 for additional details.

a. Existing and Future Conditions

In Riverside County, variations in topography, elevation, soil and climate create conditions for a wide variety of natural communities, each with its own assemblage of native plants and animals. Hence the biological resources of Riverside County include a rich range of habitats, plants, animals and insects that cover a wide spectrum, from banal (pigeons, gophers and coyotes) to highly endangered and endemic to very small portions of the county (fairy shrimp, Quino checkerspot butterfly and Stephens' kangaroo rat, for example).

Section 4.8 provides a complete description of the natural communities (habitats), species and existing conservation areas. This data includes Table 4.8-A (Western Riverside County Natural Communities), Table 4.8-B (Coachella Valley Natural Communities), Table 4.8-C (Non-MSHCP Areas Natural Communities), Table 4.8-D (Sensitive Species of the County within the WRC-MSHCP or CV-MSHCP) and Table 4.8-E (Additional Candidate, Sensitive and Special Status Species Potentially in Riverside County). It also includes Figure 4.8.1 (MSHCP Coverage Areas and Non-MSHCP Areas within Riverside County), Figure 4.8.2 (Western Riverside County Natural Communities), Figure 4.8.3 (Coachella Valley Natural Communities) and Figure 4.8.4 (Non-MSHCP Areas Natural Communities). Section 4.8 also discusses the role of environmental regulations and, in particular, the two major Multi-Species Habitat Conservation Plans (MCHCPs) that cover parts of tRiverside Ccounty: the Western Riverside County MSHCP and the Coachella Valley MSHCP.

Spatial analyses were performed to examine the cumulative results of General Plan build out on biological resources. To encapsulate the scope of impacts resulting from build out of Riverside County, the various General Plan build out scenarios were analyzed against the natural communities mapped within Riverside County (i.e., General Plan Figures OS-4a, 4b and 4c). These land use and habitat analyses reflect the range of impacts to species, as site-specific or species-specific surveys are well beyond the scope of this programmatic EIR. Table

5.5-M (Cumulative Biological Effects in Unincorporated Riverside County), below, shows the cumulative conditions for the three General Plan build out scenarios examined in this section: the existing (*2009* ~~2008~~) General Plan (CURR GP), the General Plan updated per the project (GPU/GPA960) and the cumulative General Plan as per the additional proposed GPAs through 2009 (CULM GP).

1. Encompasses coastal sage scrub, desert alkali scrub and desert scrub habitats.
2. Encompasses alkali playa and playa/vernal pool habitats.
3. Encompasses cismontane alkali marsh and meadow/marsh habitats.
4. Encompasses dry wash woodland/mesquite, riparian scrub/woodland/forest, and Riversidean alluvial fan sage scrub habitats.
5. *See Tables 7.1 through 7.4 in Appendix EIR-11 for more detailed data used in these tables.*

Source: Riverside County GIS *(RCIT)*, RCLIS layers (natural communities: western, Coachella Valley and non-MSHCP areas) and project application data, 2013 *and 2014*.

Growth pressures within Riverside County will result in development that causes the incremental loss, fragmentation and degeneration of natural habitat regardless of the General Plan build out scenario. Per Table 5.5-M, General Plan build out will contribute incrementally to the loss of species and habitat within Riverside County and result in varying degrees of impacts, depending on the size, scope and location of the incremental future development. Under build out of the current (*2009* ~~2008~~) General Plan, the amount of disturbed and developed land overall would increase 20% countywide. This includes increases in urban/suburban uses of roughly *32%* ~~63%~~ (*25,700* ~~30,600~~ acres) and *a doubling of* ~~an increase in~~ interface/wildland uses*, approximately 1.5 million acres* ~~of 48,700 acres (119%)~~. Due to greater accuracy in mapping, public facility uses would decrease *nearly 10%* ~~42%~~, which is a gain of roughly *2,400* ~~6,400~~ acres of mainly undisturbed habitat. These land use changes show similar trends across the various natural communities; that is, habitat acreage within vacant/open uses decreasing and in urban/suburban and, in particular, interface/wildland uses increasing.

The with-project General Plan build out scenario, GPU/GPA960, will further increase these amounts of habitat loss to development and urbanization in general, though in incremental amounts generally not substantial. Of

particular note, the GPU/GPA960 scenario would add over *9,200* ~~10,000~~ additional acres of natural habitat within vacant and open space uses. For the cumulative GPAs/General Plan build out (i.e., the CULM scenario), the incremental losses of native habitat and gains in developed acreage continue in larger, but still incrementally insignificant, amounts. In particular, when compared against the offsetting habitat conservation targets to be achieved through the Western Riverside County and Coachella Valley MSCHPs, the incremental effects of habitat loss for the GPU/GPA960 and CULM scenarios are not cumulatively significant.

b. Impacts

Future development accommodated will contribute incrementally to cumulative biological impacts as Riverside County builds out over time pursuant to the Riverside County General Plan (regardless of scenario). Specific impacts of the severities indicated will include the following:

(1) Cumulative Impacts Mitigated to Non-Substantial Levels

- Loss of habitat, including riparian and other sensitive habitat types. See discussion under Impact 4.8.A in Section 4.8.

- Direct take of species (that is, kill, harass, harm, etc.), including species protected by law (threatened or endangered under the federal or California Endangered Species Act), as well as species otherwise protected or identified as sensitive (e.g., within the WR-MSHCP or CV-MSHCP, etc.). See discussion under Impact 4.8.B.

- Indirect "take" of species (through habitat loss, loss of breeding, nesting or roosting areas, noise and disturbance by humans, pets, etc.), including protected and sensitive species. See discussion under Impact 4.8.B.

- Adverse effects to, including loss of, wetlands and riparian habitat through direct removal, fill or hydrological interruption; or indirectly through topographic changes, alteration of soils, slopes or hydrology; etc. See discussion under Impact 4.8.C.

- Adverse effects to, including loss of, areas used for the movement of both resident and migratory native species of fish and wildlife. This includes loss of wildlife corridors and open space lands connecting natural habitat areas, as well as the use of wildlife nursery and hibernation sites. See discussion under Impact 4.8.D.

(2) Non-Substantial Cumulative Impacts

The following effects will contribute incrementally, but not substantially, to the cumulative impact on biological resources occurring as a result of build out of the Riverside County General Plan. See Section 4.8.6 for additional details on these impacts.

- Loss of habitat directly, e.g., through conversion of natural habitats to developed uses or the clearing of native vegetation; indirect habitat loss (e.g., through alteration of drainage and hydrology, introduction of invasive plants species [weeds] or due to increased disturbance by human activities, etc.); as well as habitat fragmentation (loss of continuity among natural habitats, resulting in "edge effects").

- Edge effects in which human activities (particularly development of previously vacant lands) introduce disturbances in the vicinity of natural plant communities and wildlife habitat. Noise, trash and refuse, light pollution, predation by house pets and human encroachment are all associated with edge effects.

- Loss of oak trees and other mature forest canopy, either through direct take or through indirect causes, such as hydrological changes, etc.

c. Mitigation

As described in detail in Section 4.8 (see Section 4.8.3), a variety of existing regulatory compliance and specific mitigation measures would be implemented to avoid, reduce and minimize adverse cumulative biological impacts. These include the following:

(1) Regulatory Compliance

Key Regulations and Programs:

- Federal Endangered Species Act
- Federal Clean Water Act (Sections 401, 402 and 404, in particular)
- Migratory Bird Treaty Act
- California Endangered Species Act - CFGC section 2050 *et seq.*
- California Fish and Game Code (CFGC), section 1600, *et seq.*
- Natural Community Conservation Planning Act
- California Native Plant Protection Act.
- Western Riverside County Multi-Species Habitat Conservation Plan
- Coachella Valley Multi-Species Habitat Conservation Plan
- Stephens' Kangaroo Rat Habitat Conservation Plan
- Riverside County Oak Tree Management Guidelines
- Ordinance No. 559 - Regulating the Removal of Trees

Key General Plan Policies: See Section 4.8.3 for text of each policy.

- Land Use Element Policies: LU 7.7, 9.1 and 9.2
- Open Space Element Policies: OS 5.1-5.3, 5.5, 5.6, 6.1, 6.2, 9.3, 9.4, 17.1, 17.2, 18.1, 18.3, 18.4 and 20.2
- Circulation Element Policies: C 20.9

(2) CEQA Mitigation

As part of EIR No. 521, the following new mitigation measures (MMs) are proposed to ensure that biological impacts are reduced to less than significant. See the cited impacts in Section 4.8.6 for the full text of each mitigation measure.

- **New MM 4.8.A-N1:** For sites not governed by an existing MSHCP, where site conditions (for example, topography, soils, vegetation, etc.) indicate a project could adversely affect any riparian or riverine resources, then an appropriate assessment shall be prepared by a qualified professional. An assessment shall include, but not be limited to, identification and mapping of any riparian/riverine areas and evaluation of species composition, topography/hydrology and soil analysis, as applicable. An assessment shall be completed as part of the environmental review for the development proposal prior to its approval. Upon receipt of an assessment, the Riverside County Ecological Resources Specialist (ERS) shall review the document and make a finding that either:

  a. Riparian/riverine areas do not exist on site;

  b. Project-specific avoidance measures have been identified that would be sufficient to ensure avoidance of riparian/riverine areas; or

  c. Impacts to riparian/riverine areas are significant and unavoidable. If avoidance is not feasible, a practicable alternative that minimizes direct and indirect effects to riparian/riverine areas and vernal pools and associated functions and values to the greatest extent possible must be developed.

  If impacts remain significant and unavoidable then the ERS will require the project applicant to obtain a Section 404 permit from the ACOE and/or a Fish and Game Code Section 1600 agreement from CDFW prior to the issuance of any grading permit or other action by the County of Riverside that would lead to the disturbance of the riparian resource.

- **New MM 4.8.A-N2:** For sites not governed by an MSHCP, a general biological resources assessment (BRA) shall be required as part of the discretionary project review process at the County of Riverside's discretion. For example, if site inspection, aerial or other photos, resource agency data or any other information indicates potential for sensitive habitat to occur on, or be adversely affected by the proposed project. The BRA shall be prepared and reviewed as per the requirements outlined in Mitigation Measure 4.8.B-N1.

- **New MM 4.8.B-N1:** Prior to discretionary project approval for projects with the potential to substantially adversely affect sensitive (listed, candidate or special status) species or habitats not covered by an existing MSHCP or HCP, a general biological resource assessment (BRA) shall be performed. The following requirements shall apply:

  a. The BRA shall be performed by a Riverside County-approved biologist pursuant to a Memorandum of Understanding (MOU) executed between the biologist and the County of Riverside.

  b. The biology/environmental firm or biologist preparing the BRA must be on the County of Riverside's list of qualified consultants.

  c. Fieldwork must be performed by qualified biologists according to professional standards.

d. If included in the BRA, presence/absence surveys for specific plants must be conducted during the applicable blooming season or other conditions as deemed scientifically appropriate and valid.

e. Should affected species or habitat occur on the project site, then a "Focused Protocol Survey" must be prepared for those species using existing protocols established by the USFWS or CDFGCDFW. If no such protocols exist, the survey must be based on generally accepted biological survey protocols appropriate to the species.

The BRA requirement *may* be waived if any of the following conditions are documented to exist.

a. The area affected by the proposed project ("footprint" herein) consists entirely of built environment (structures, pavement, etc.) and none of the biota or plant material present (i.e., landscaping) represent likely habitat used by a sensitive species.

b. The Riverside County Environmental Resource Specialist (ERS) finds in writing that the proposed footprint does not have any biological resources expected to be used by a protected species or plant.

c. The project or activity proposed is to be performed under an existing incidental take permit, habitat conservation plan or other governing permit, license or authorization (i.e. Section 7 consultation) and no new significant effect to the covered species or other protected species or resource is expected to occur.

In addition to the items herein, the BRA shall also be prepared in accordance with the Riverside County "Guide to Preparing General Biological Resource Assessments," as well as any other requirements of the Riverside County Environmental Programs Department, Planning Department or other County of Riverside agency.

Upon receipt of the BRA, the Riverside County ERS shall review it and all supporting documentation. If the Riverside County ERS finds that the project does not have the potential to substantially affect sensitive species or habitat, no further mitigation is required. If the Riverside County ERS finds that the project has the potential to substantially adversely affect sensitive species or habitat, then additional mitigation will be developed and imposed to reduce such impacts to below a level of significance. Such mitigation may include but not be limited to obtaining an incidental take permits from the USFWS and/or CDFW, as applicable and acquisition and conservation of replacement habitat at appropriate ratios.

- **New MM 4.8.C-N1:** If site conditions (for example, topography, soils, vegetation, etc.) indicate that the proposed project could affect riparian/riverine areas or federally protected wetlands as defined by Section 404 of the CWA, then an appropriate assessment shall be prepared by a qualified professional as part of Riverside County's project review process. An assessment shall include, but not be limited to, identification and mapping of any wetland(s) or riparian resources present; evaluation of plant species composition, topography and hydrology; a soils analysis (where appropriate) and conclusions stating the presence or absence of jurisdictional wetlands. An assessment shall be completed as part of the CEQA review for the development proposal.

  Should any grading or construction be proposed within or alongside the banks of the watercourse or wetland, the land divider/permit holder shall provide written notification to the Riverside County Planning Department that the alteration of any watercourse or wetland, located either on site or on any required offsite improvement areas, complies with the U.S. Army Corp of Engineers Nationwide Permit

Conditions. Or, the land divider shall obtain a permit under Section 404 of the Clean Water Act. Copies of any agreements shall be submitted along with the notification.

- **New MM 4.8.C-N2:** If site conditions (for example, topography, soils, vegetation, etc.) indicate that the proposed project could affect riparian/riverine areas or federally protected wetlands as defined by CFGC Section 1600 *et seq*., then an appropriate assessment shall be prepared by a qualified professional as part of Riverside County's project review process. An assessment shall include, but not be limited to, identification and mapping of any wetland(s) or riparian resources present; evaluation of plant species composition, topography and hydrology; a soils analysis (where appropriate) and conclusions stating the presence or absence of jurisdictional wetlands. An assessment shall be completed as part of the CEQA review for the development proposal.

  Should any grading or construction be proposed within or along the banks of any natural watercourse or wetland located either on site or on any required offsite improvement areas, the land divider/permit holder shall provide written notification to the Riverside County Planning Department that the appropriate California Department of Fish and Wildlife notification pursuant to Sections 1601/1603 of the California Fish and Game Code has taken place. Or, the land divider shall obtain an "Agreement Regarding Proposed Stream or Lake Alteration" (Section 1601/1603 Permit). Copies of any agreements shall be submitted along with the notification.

- **New MM 4.8.D-N1:** Should a wildlife nursery site or native resident or migratory wildlife corridor be uncovered through a biological resources assessment (BRA), then a consultation with a Riverside County Ecological Resources Specialist (ERS) shall occur. The ERS shall make a determination if the site is essential for the long term viability of the species. If such a determination is made, then the ERS shall work with the applicant to avoid the effects of development on the resource in question and condition the land use case accordingly. Should significant impacts to nursery site or corridor not be avoidable, project applicant shall be required to ensure the preservation of comparable nursery or corridor habitat off site.

d. Significance

Implementation of all of the above regulations, General Plan policies and mitigation measures, would be sufficient to ensure that all of the incremental cumulative impacts listed above would be less than significant. Thus, build out of any of the above General Plan scenarios would contribute incrementally but not substantially to cumulative impacts.

8. Cumulative Effects on Cultural and Paleontological Resources

Section 4.9 (Cultural and Paleontological Resources) discusses existing cultural resources, including historical and archeological, within Riverside County, as well as the data sources used and any updates to them. The section also analyzes impacts from future development accommodated by the changes proposed by the project, GPA No. 960, as well as the mitigation (both regulatory and CEQA-specific) necessary to ensure impacts are less than significant. As a result, topics already covered in Section 4.9 are not repeated here.

Section 4.9 provides a complete description of the cultural and paleontological resources known or expected to occur in Riverside County. This data includes Table 4.9-A (Cultural Resources of Riverside County) and Table 4.8-B (Paleontological Resources By Age, Formation and Location). It also includes Figure 4.9.2 (Historical Resources in Riverside County) and Figure 4.9.3 (Paleontological Sensitivity).

a. Existing Conditions

Cultural resources include areas, places, sites (particularly archeological sites), buildings, structures, objects, records or manuscripts associated with history or prehistory. Cultural resources may also include places that have historic or traditional associations or that are important for their natural resources. Paleontological resources consist of evidence of past life forms and their biota. They yield valuable information about the history of the earth and its past ecological settings. The cultural resource characteristics of Riverside County reflect patterns of human settlement, human use of the land and its resources, the artistic expressions on material culture and natural features, technologies and ideologies, as well as past environmental conditions. The existing paleontological setting reflects the paleontological record and related geology as they are currently known for Riverside County.

Historical and Archeological Resources: The large number of known prehistoric resources in Riverside County are documented via CHRIS, the California Historical Resources Information System, which is archived and maintained by the Eastern Information Center (EIC) at the University of California, Riverside (UCR); a branch of the California Office of Historical Preservation. Of these recorded sites within Riverside County, a few have been designated as federal, state and/or county cultural resources, as shown in Table 4.9.A in Section 4.9.

Prehistoric resources, artifacts and features include evidence of the 14,000-plus years of occupation and transient use by Native American populations. The Ethnohistoric Period of Riverside County at the time of Euro-American contact was distinguished by eight distinct resident cultural groups of Native Americans which occupied territories across Southern California and Riverside County. See Section 4.7 of EIR No. 441 for further background on these ethnological groups and cultures.

The advent of written documentation of events separates the Historic Era from the Prehistoric Period. In Riverside County, the Historic Era is generally said to begin around 1772, with the European exploration of the western coast of North America. As settlement patterns became established, systems of documentation became more regularized and increasingly preserved, creating a body of "historical record" from which historical resources may be ascertained, rediscovered and documented. In addition, many historic structures and sites dating from only the last century or so are extant (still standing), with many buildings still being used.

Table 4.9.A in Section 4.9 provides a catalog of the various cultural resources that have been listed within Riverside County, including the cities. Because of the vast size of Riverside County, Table 4.9.A only includes known listed sites/resources recognized at the levels indicated and should not be considered exhaustive or exclusive. In particular, the potential also exists for sites in Riverside County to have previously unknown archeological and historical resources present either on the surface or below ground. It is expected that a large number of archeological and historical resources occur within Riverside County that are currently undiscovered or unknown, particularly for resources located below the ground's surface. For sub-surface resources, discovery most often only occurs if the site is disturbed, such as through archeological investigation, or as more commonly happens, when construction activities such as grading or trenching are initiated.

Paleontological Resources: Fossils, which are nonrenewable paleontological resources, are important for dating sedimentary rocks and thus determining the time of movement of faults against which those sediments lie. Riverside County has an extensive record of fossil life. Eastern and western Riverside County have fossiliferous sediments that occur in various settings. In the western portion of Riverside County, fossils occur in sediments lying on the surface of crystalline bedrock or are deposited in or between the major fault zones. The eastern desert portions of Riverside County are marked by fault block mountains that contain older fossil-bearing sediments with younger fossil-containing deposits found around dry lakes, along high stands of the Salton Sea and in terraces left by the Colorado River. The geological eras represented by the fossil records found in Riverside

County are briefly summarized as follows, and as shown in Table 4.9.B. Figure 4.9.3 identifies the sensitivity of lands within Riverside County in relation to the potential for finding paleontological resources.

b. Future Conditions

Effects to *known* cultural resources (historical, archeological and paleontological) can be mitigated to less than significant levels through the regulatory and mitigation measures outlined in Section 4.9. However, since most cultural resources occur below ground (particularly paleontological resources, which are heavily geology-dependent), most cultural resources remain *unknown* and undiscovered until uncovered by ground-disturbing activity, for example site grading, road construction or trenching for pipelines. As a result, the likelihood of subsurface resource disturbance by future development typically cannot be fully determined in advance, particularly within the scope of this countywide programmatic EIR. Rather, such determinations will have to be made at the individual implementing project stage and addressed (mitigated) via the mechanisms outlined in Section 4.9. The cultural resources section (4.9) presents explicit, mandatory measures that must be taken when an artifact or other cultural resource is unearthed.

Nevertheless, since paleontological resources do correlate with geology, a generalized assessment of relative paleontological sensitivity was developed for much of Riverside County (i.e., see Figure 4.9.3) and the existing and proposed land uses associated with the various General Plan build out scenarios was assessed against this sensitivity to examine cumulative impacts. The results of this analysis are shown in Table 5.5-N, below.

The results indicate that build out of the existing General Plan (CURR GP) will result in disturbance of a great deal of additional land with high paleontological sensitivity (e.g., Ha or Hb). In particular, acreage devoted to urban/suburban uses will roughly double and the area potentially developed within the interface/wildland fringes of Riverside County will increase roughly ten-fold (23,000 to *nearly* 234,000 acres). Lastly, the area left vacant and open will decrease by roughly two-thirds.

For the updated General Plan (i.e., with-project) and cumulative General Plan build out scenarios (GPU/GPA 960 and CULM GP), similar trends will occur, however in much smaller amounts. The incremental increases associated with the individual future projects pursuant to these scenarios will be individually insignificant. However, cumulatively they will amount to upwards of 3% to 8% of the total area by category. Specifically, for the GPU/GPA960 scenario, uses within high-sensitivity areas will increase roughly *1%* ~~3%~~ in urban/suburban areas and *nearly 5%* ~~over 6%~~ for public facility uses. Though offset by a nearly 8% increase in open space and nearly 6% less development within interface/wildland areas, the overall cumulative effects to paleontologically sensitive lands will still be considerable. Similar trends are seen for the CULM scenario, with slightly higher amounts of urban/suburban and rural/agricultural uses (*5%* ~~4%~~ *and 1%* ~~3%~~, respectively) and no offsetting increase in vacant/open space ~~(rather, an additional 1% would be loss)~~. Public facility lands would *also remain about the same.* ~~decrease by roughly 4%, however this amounts to less than 500 acres, which is not enough to offset cumulatively considerable effects countywide.~~

Table 5.5-N: Cumulative Paleontological Effects in Riverside County

c. Impacts

Future development accommodated will contribute incrementally to cumulative impacts to cultural and paleontological resources as the county builds out over time pursuant to the Riverside County General Plan (regardless of scenario). Specific impacts of the severities indicated will include the following:

(1) Cumulatively Considerable Impacts

- Land disturbances from construction of new development would uncover and/or adversely affect presently unknown historic or archeological resources. See discussion under Impacts 4.9.A and 4.9.B in Section 4.9.

- Future development would result directly or indirectly in the destruction of unique paleontological resources, sites or unique geological features, particularly previously unknown subsurface resources. See discussion under Impact 4.9.C.

- Lastly, since uncovered human remains can also be of modern origins, and hence potentially part of a crime scene, specific County of Riverside regulations require contacting the Riverside County Coroner's Office for initial assessment of any uncovered human remains. Specifically, HSC Section 7050.5(b) states that no further disturbance shall occur until the Riverside County Coroner has made the necessary findings as to origin. Further, pursuant to PRC Section 5097.98(b), remains shall be left in place and free from disturbance until a final decision as to their treatment and disposition has been made. If the remains are determined not to be modern, subsequent treatment of the discovery is handled in coordination with the Tribe determined by the State of California to be the "Most Likely Descendent," see Existing MM 4.9.1A for additional details.

(2) Non-Substantial Cumulative Impacts

- Land disturbances from construction of development would adversely affect known historic and archeological resources. See discussion under Impacts 4.9.A and 4.9.B.

- Future development could disturb undiscovered human remains, including those interred outside of formal cemeteries. Remains can be historic, prehistoric or modern. All remains are first examined by the Riverside County Coroner's Office. Those deemed modern are handled as a criminal case. Those deemed archeological (historic or prehistoric) are handled per applicable regulations, in particular those addressing Native American and ancestral remains. See Impact 4.9.D discussion.

d. Mitigation

As described in detail in Section 4.9.3, a variety of measures would be implemented to avoid, reduce and minimize adverse cumulative impacts to cultural and paleontological resources. These include the following:

(1) Regulatory Compliance

Key Regulations and Programs: See Section 4.9.3 for details on each regulation.

- National Historic Preservation Act
- Native American Graves Protection and Repatriation Act
- Title 33, Code of Federal Regulations (Section 325, Appendix C)
- Traditional Tribal Cultural Places Act – GC Section 65352.3)
- California Public Resources Code, Section 5097 - Regulating Paleontological Resources
- California Environmental Quality Act – CCR, section 15064.5
- Ordinance No. 578 - Historic Preservation Districts

Key General Plan Policies: See Section 4.9.3 for text of each policy.

- Land Use Policies: LU 4.5
- Open Space Policies: OS 19.2 – 19.9

(1) Regulatory Compliance

Existing Mitigation Measures: As part of EIR No. 441 certified for the RCIP General Plan adopted October 2003, the following mitigation measure (MM) applies to future development.

- **Existing MM 4.7.1B:** Avoidance is the preferred treatment for cultural resources. Where feasible, project plans shall be developed to allow avoidance of cultural resources. Where avoidance of construction impacts is possible, capping of the cultural resource site and avoidance planting (e.g., planting of prickly pear cactus) shall be employed to ensure that indirect impacts from increased public availability to the site are avoided. Where avoidance is selected, cultural resource sites shall be placed within permanent conservation easements or dedicated open space.

New Mitigation Measures: As part of EIR No. 521, the following new mitigation measure (MM) is proposed to ensure that impacts are reduced to less than significant where feasible.

- **New MM 4.9.B-N1:** If avoidance and/or preservation in place of cultural resources is not feasible, the following mitigation measures shall be initiated for each impacted site:

  a. Discoveries shall be discussed with the Native American tribal (or other appropriate ethnic/ cultural group representative) and the Riverside County Archeologist, and a decision shall be made with the concurrence of the Planning Director, as to the appropriate mitigation (documentation, recovery, avoidance, etc.) appropriate for the cultural resource.

  b. Further ground disturbance shall not resume within the area of the discovery until an agreement has been reached by all parties as to appropriate preservation or mitigation measures.

e. Significance

The analysis above indicates that future development consistent with any of the General Plan build out scenarios analyzed, including the proposed project (GPA No. 960), would contribute to a variety of incremental impacts related to cultural resources. The regulatory and mitigation measures presented in Section 4.9 were deemed sufficient to ensure that a project's individual cultural impacts can be avoided, reduced or minimized to less-than-significant levels. Cumulatively considerable impacts will occur as Riverside County grows pursuant to the General Plan, regardless of the scenario. The removal or destruction of cultural resources and the cumulative effect of their disturbance cannot be guaranteed to be reduced to less than significant levels even with mitigation. This is due to the unknown nature of the extent, location and cultural significance of such resources. For these reasons, both the updated General Plan build out scenario (encompassing the changes proposed by the project, GPA No. 960), as well as the cumulative General Plan scenario (i.e., updated per the GPAs listed previously), would contribute substantially to significant cumulative impacts to previously unknown historical, archeological, cultural and paleontological resources.

9. Cumulative Effects on Energy Resources

Section 4.10 (Energy Resources) discusses existing energy resources and demands within Riverside County, as well as the sources used for this data and any updates made. The section also addresses the energy conservation issues identified in State CEQA Guidelines, Appendix F. It also analyzes energy impacts from future development accommodated by the changes proposed by the project, GPA No. 960, as well as the mitigation (both regulatory compliance and EIR mitigation) necessary to ensure impacts are less than significant. Topics covered in Section 4.10 are not repeated here.

Section 4.10 includes a complete description of the energy resources generated in Riverside County, as well as an analysis of the resources used currently and projected to be needed as the county builds out. This data includes Table 4.10-A (Summary of Electrical Production), Table 4.10-B (Southern California Edison System Projects), Table 4.10-C (Imperial Irrigation District Electricity System Projects), Table 4.10-D (Energy Consumption by Major Energy Provider), Table 4.10-E (Theoretical Annual Electricity Demand for Existing Uses of Land), Table 4.10-F (Theoretical Annual Electricity Demand for Proposed Land Use Build Out), Table 4.10-G (Theoretical Annual Natural Gas Demand for Existing Uses of Land) and Table 4.10-H (Theoretical Annual Natural Gas Demand for Proposed Land Use Build Out). It also includes Figure 4.10.1 (Electricity Providers Serving Riverside County) and Figure 4.10.2 (Energy Transmission Corridors and Lines). Section 4.10 also discusses the role of energy regulations and conservation.

a. Existing Conditions

Provision of adequate power and energy is a significant component of public services in Riverside County. The following section describes the current power and energy resources serving unincorporated Riverside County, including electricity, natural gas and alternative energy sources.

According to the California Energy Commission (CEC), all of the fossil-fuel powered electrical generators in Riverside County use natural gas as the "primary fuel" in their "oil/gas" type facilities. Some of the generating facilities located outside Riverside County that provide electricity for use in Riverside County use other fossil fuels, including diesel and coal, in addition to natural gas, as well as a variety of alternate (renewable) energy sources. The CEC tracks usage of renewable energy resources which include: biomass and waste, geothermal, solar, wind and "small hydroelectric," which the CEC defines as facilities generating under 30 megaWatts (MW).

b. Future Conditions

Typically, the introduction of new development into an area brings with it an attendant new demand for energy resources, including natural gas and, in particular, electricity. Development may also utilize propane and other fuels. Accordingly, spatial analysis was performed to examine the cumulative demands of General Plan build out on energy resources. To encapsulate the scope of impacts resulting from build out, the various General Plan build out scenarios were analyzed for theoretical use/demand for the energy resources. These energy analyses reflect the range of impacts associated with the *theoretical* demand for energy (electricity and natural gas) for the specific land uses indicated for each scenario. For specifics on methodology used, see Section 4.10.4.

Tables 5.5-O and 5.5-P, below, show *build out* ~~the cumulative~~ conditions for the three General Plan ~~build out~~ scenarios examined in this section: Existing General Plan (CURR GP), the updated General Plan as per GPA No. 960 (GP/GPA960) and the cumulative General Plan as per the additional proposed GPAs through 2009 (CULM GP). It should be noted that the baseline (existing) energy levels listed in the table are theoretical, i.e.,

based on standardized modeling. The same modeling procedures were used to estimate results for each of the build out scenarios. By controlling these variables, valid comparisons amongst the scenarios are possible.

These data should not be construed as the *actual* energy usage for a given location, a specific existing use or its future development. Privacy laws protect such information from being publicly released for private properties. Further, specific information is typically provided by the associated utility provider when an implementing development is proposed. Each utility provider has developed its own methods, formulae and factors for projecting future demand, which are neither available nor practicable for calculating for this programmatic EIR. In general, however, where the proposed project is consistent with regional (Southern California Association of Governments [SCAG]) and county growth projections, it is assumed long-range planning undertaken by individual utilities and service providers would be sufficient to meet future needs, since they also reference these same SCAG and county projections.

The results of the energy modeling (electricity and natural gas, the only two energy sources for which sufficient information was available for accurate modeling) for baseline (existing) conditions and the various cumulative build out scenarios are presented in Tables 5.5-O and 5.5-P, respectively. All data represent direct energy usage. Indirect energy uses, such as by water providers, are addressed separately at the regional scale (e.g., see Section 4.7). Because energy use depends on the technology, generation source, service area size and a number of other factors, specific indirect energy use projections are not feasible as part of this programmatic EIR. See Section 4.10.4 for specifics on the assumptions used in these analyses.

Table 5.5-O: Cumulative Effects on Theoretical Electricity Demand

ELECTRICITY DEMAND *(in MWh/y)*[1,2]	Existing Conditions	%	General Plan Build Out Scenarios					
			CURR GP[3]	%	GPU / GPA960[3]	%	CULM GP[3]	%

Industrial[4]	*2,419,000*	*36%*	*338,400*	*49%*	*3,398,000*	*49%*	*3,472,000*	*46%*
ECONOMIC - subtotal	***5,627,000***	***83%***	***3,967,000***	***58%***	***3,997,000***	***58%***	***4,643,000***	***61%***
Total	***6,791,400***		***6,892,100***		***6,866,100***		***7,587,400***	
ENVI Δ (Difference from EXIST)	---	---	*+100,700*	*+1%*	*+74,700*	*+1%*	*+796,000*	*+12%*
GP Δ (Difference from CURR)	---	---	---	---	*-26,000*	*-0.4%*	*+695,300*	*+10%*

Footnotes:
1. MWh/y = megawatt-hours per year (rounded to nearest 100).
2. Electricity Factors: Residential 5,626 kWh/y/du; Commercial 13.20 kWh/y/sf; Industrial 10.50 kWh/y/sf.
3. CURR GP = General Plan as of end of *2009* ~~2008~~. See Section 5.5.1 for descriptions of each GP scenario.
4. Commercial uses include CR, CO & CT. Industrial uses include HI, LI & BP. Uses too variable for factors omitted.
5. *See Table 18.1 in Appendix EIR-11 for more detailed data used.*

Source: Riverside County Planning Dept., Project Application Data, 2013 *and 2014*.

As shown in Tables 5.5-O and 5.5-P, General Plan build out (of any scenario) will contribute incrementally to the demand for energy resources within Riverside County and result in varying degrees of impacts in order to meet such demand, depending on the size, scope and location of the incremental development proposed. For both the with-project scenario (GPU/GPA960) and the cumulative GPAs scenario (CULM GP), General Plan build out would result in cumulatively considerable increases in demand for both electricity ~~(+21%)~~ and natural gas ~~(+23%)~~ to serve the additional residential units that would result, even though individual increases associated with implementing projects over time would be incrementally insignificant. For natural gas, the CULM scenario would also significantly increase incremental demand as a result of additional commercial development.

It should be noted that the theoretical demands estimated in the above tables are based on worst-case (business-as-usual) scenarios that do not take into account any energy efficiency and other conservation standards enacted by the County of Riverside or State of California. As outlined in Section 4.7, implementation of specific building energy-efficiency standards outlined in Riverside County's proposed Climate Action Plan and other energy-related measures affecting electricity supplies, are documented to reduce 2020 electricity demands by nearly half (48%). A full discussion of these measures, including their relationship to existing and proposed energy conservation efforts of both the State of California and the County of Riverside, is provided in Section 4.7.

Table 5.5-P: Cumulative Effects on Theoretical Natural Gas Demand

3. CURR GP = General Plan as of end of *2009* ~~2008~~. GPU/GPA960 = Current General Plan as amended per GPA No. 960. CULM GP = Current General Plan as amended per list of active GPAs. See Section 5.5.1 for full descriptions of each.
4. Commercial uses include CR, CO & CT. Industrial uses include HI, LI & BP. Uses too variable for factors omitted.
5. *See Table 18.2 in Appendix EIR-11 for more detailed data used.*

Source: Riverside County Planning Dept., Project Application Data, 2013 *and 2014*.

c. Impacts

Future development will contribute incrementally to cumulative energy demand and impacts on electricity and natural gas infrastructure as Riverside County builds out over time pursuant to the Riverside County General Plan (regardless of scenario). Specific impacts of the severities indicated will include the following:

(1) Cumulatively Considerable Impacts

- Build out of any of the General Plan scenarios will introduce new development and intensify existing development on previously vacant or less-developed lands, incrementally increasing the demand for electricity over time.

- Build out of any of the General Plan scenarios will also introduce new development and intensify existing development on previously vacant or less-developed lands, increasing the demand for natural gas.

(2) Non-Substantial Incremental Impacts

- As Riverside County builds out pursuant to any of the General Plan scenarios, energy demand increases, additional transmission lines and pipelines for conveying electricity, natural gas, etc., may be necessary to adequately meet energy demands.

- The project (and hence, the GPU/GPA960 scenario) proposes new policies and programs targeting energy efficiency and conservation directly in order to reduce greenhouse gas emissions by roughly 30% (see EIR Section 4.7, Greenhouse Gases). As a result of implementation of such measures, new development would be more energy-efficient and less wasteful of energy than existing uses or proposed uses without GPA No. 960. Thus, in terms of energy efficiency and conservation, the project would result in incremental net benefits from these additional energy savings.

d. Mitigation

As described in detail in Section 4.10.3, a variety of measures would be implemented to avoid, reduce and minimize adverse cumulative energy resource impacts. These include the following:

(1) Regulatory Compliance

Key Regulations and Programs: See Section 4.10.3 for details on each regulation, as well as Section 4.7.3 for details on energy conservation measures derived from greenhouse gas reduction efforts within Riverside County.

- California Energy Code – CCR Title 24, Part 6: Forms the California Energy Code, (often referred to simply as "Title 24," for short). Formally titled "California's Energy Efficiency Standards for Residential and Nonresidential Buildings."
- California Green Building Standards Code - CCR Title 24, Part 11: Encompasses the "California Green Building Standards Code."
- California's Renewables Portfolio Standard - Senate Bill 1078 (2002)
- California's Renewable Energy Transmission Initiative (RETI)
- Riverside County Climate Action Plan (proposed in conjunction with GPA No. 960)
- Riverside County Wind Implementation Monitoring Program (WIMP)
- Board of Supervisors (BOS) Policy H-29 - Sustainable Building Policy
- BOS Policy H-4 - Conservation of Energy in County Facilities
- Riverside County Weatherization Program
- Riverside County Low Income Energy Assistance Program

Key General Plan Policies: See Section 4.10.3 for the text of each policy.

- Air Quality Element Policies: AQ 4.1-4.4, 5.2-5.4, 13.1, 18.3-18.5, 19.3, 20.10-20.12, 20.18-20.21 and 20.25-20.28
- Open Space Element Policies: OS 10.1, 10.2, 11.1-11.4, 12.1-12.4 and 16.1-16.14

(2) CEQA Mitigation

The following CEQA mitigation measures (MMs) were adopted as part of certification of EIR No. 441 for the RCIP General Plan in October 2003 and remain applicable to GPA No. 960 and future General Plan implementing projects:

- **Existing MM 4.8.1A:** The County [of Riverside] shall review all development proposals prior to the approval of development plans to guarantee that sufficient energy resources and facilities are available to supply adequate energy to the proposed project and associated uses.

- **Existing MM 4.8.1B:** The County [of Riverside] shall review all development plans prior to approval to guarantee that energy conservation and efficiency standards of Title 24 are met and are incorporated into the design of the future proposed project.

e. Significance

Implementation of all of the above regulations, General Plan policies and mitigation measures, would be sufficient to ensure that all of the incremental (non-substantial) cumulative impacts listed above would be less than significant. In particular, the project's incremental contribution to energy conservation efforts would be cumulatively beneficial. In terms of increased demand for energy, in particular electricity and natural gas, build out of any of the above General Plan scenarios would result in cumulatively considerable impacts to energy resources.

10. Cumulative Effects on Flood and Dam Inundation Hazards

Section 4.11 (Flood and Dam Inundation Hazards) discusses existing flooding and dam inundation hazards within Riverside County, as well as the sources used (and any updates made to them) for this data. The section also addresses flooding related hazards, such as seiche, mudflow, etc., and analyzes flood hazards that would arise from future development accommodated by the project, GPA No. 960, as well as measures (both regulatory and mitigation) to ensure impacts are less than significant. Thus, areas already covered in Section 4.11 are not repeated here. Hydrology, water quality and storm drainage issues are discussed in Section 4.19 (Water Resources).

Section 4.11 provides a complete description of flood-related hazards affecting Riverside County, as well as analysis of the existing and future flooding risks projected to occur as Riverside County builds out. This data includes Table 4.11-A (Potential Flooding Sources Studied in Riverside County), Table 4.11-B (National Inventory of Dam Data) and Table 4.11-C (Local Flood Risk Management Agencies). It also includes Figure 4.11.1 (100-Year Flood Hazard Zones) and Figure 4.11.2 (Dam Inundation Failure Zones in Riverside County).

a. Existing Conditions

In Riverside County, the three largest drainages of concern for main-stream flooding are the Santa Ana River, San Jacinto River and Whitewater River. In the western portion of Riverside County, the large rivers are dry most of the year and only pose flood threats to developments within the floodplain during general storms of long duration. In the western county, these include the Santa Ana, San Jacinto, San Gorgonio and Santa Margarita Rivers, as well as Temescal and Murrieta Creeks. Lake Elsinore and other lakes, as well as various alluvial fans throughout Riverside County, are also susceptible to flooding, for example Millard Canyon. Major floods along the San Jacinto River resulting from intense rainfall have been shown typically to peak in approximately 1.5 days with a total duration of flooding of four days.

Eastern Riverside County, being marked by extensive desert, does not possess as many major flood-prone drainages; the Whitewater and Colorado Rivers being the two principal ones. Rather, because of the arid climate and extremely porous (sandy) soils, water flows tend to pass rapidly through the region. Tributaries to the major rivers present additional flood hazards, mostly caused by local thunderstorms. Within Coachella Valley, there are many smaller washes that run out of the surrounding mountains and down into the valley floor, in some cases emptying into Whitewater River to the northwest or the Salton Sea to the southeast. The desert areas extending to the east from the Palm Springs area are also susceptible to sheet flow flooding, with flow depths of generally less than 2 feet. These types of flows leave the mouths of canyons and often follow unpredictable paths. Lastly, the desert also contains numerous washes (for example, Morongo Wash) and alluvial fans that are susceptible to flooding.

Additionally, many of the smaller drainages throughout Riverside County, particularly those running through the alluvial fans that flank Riverside County's hillsides, are susceptible to smaller-scale floods and also flash-flooding. Figure 4.11.1 in Section 4.11 shows the areas of Riverside County considered potentially at risk for flooding based on information from FEMA mapping, plus DWR and County of Riverside data. Key waterbodies are described in Section 4.11.2 and a list of all potential flooding sources studied by FEMA are provided in Table 4.11-A.

b. Future Conditions

Mainstream Flooding and Dam Inundation: Table 5.5-Q (Cumulative 100-Year Floodplain Effects), below, shows the cumulative conditions for the three General Plan build out scenarios examined in this section: Existing (*2009* ~~2008~~) General Plan (CURR GP), the updated General Plan as per GPA No. 960 (GP/GPA960) and the cumulative General Plan as per the additional proposed GPAs through 2009 (CULM GP), as well as GPA No. 960. As outlined in Table 5.5-Q, General Plan build out (regardless of scenario) will contribute incrementally to hazards due to development within areas prone to flooding, dam inundation, seiche, alluvial fan flooding, mudflow and other related conditions. Through the means outlined in Section 4.11.5, future development occurring pursuant to any of the General Plan build out scenarios would incrementally introduce additional people, property, homes, public facilities, roads and other infrastructure into 100-year flood hazard areas.

For build out of the current General Plan, the data indicate that the amount of land proposed for urban and suburban uses situated within the current 100-year floodplain would more than double (increase 126%). Interface/Wildland uses proposed within the floodplain would increase even more (nearly 740%) and Vacant/ Open Space lands within floodplains would decrease 75% (mainly due to conversion to developed uses). The CULM build out scenario shows similar trends.

Table 5.5-Q: Cumulative 100-Year Floodplain Effects

SCENARIO	Urban / Suburban	Rural / Agriculture	Interface / Wildlands	Vacant / Open Space	Public Facilities	Totals
EXIST (Existing Uses of Land)

Footnotes:
1. That is, the General Plan as of end of *2009* ~~2008~~.
2. Includes updates to floodplain as proposed in GPA No. 960 (see changes described in Section 4.11.4).
3. *"IN" denotes land in any 100-year floodplain, Flooding Zone A or dam inundation zone.*
4. *"OUT" is derived from total area data for each land use group (USUB, RURAG, etc.) from Table 4.1 (Agriculture).*
5. *See Tables 9.1 through 9.3 in Appendix EIR-11 for more detailed data used in these tables.*

Source: Riverside County Planning Dept., project application data, 2013 *and 2014*. *RCIT* GIS Dept., RCLIS layer, 100-Year Floodplains (updated), 2012.

Since the General Plan build out horizon is approximately 2060, this means that the flooding and inundation risks associated with these areas would increase incrementally over 50 years. If development were allowed to occur in an unregulated fashion, county growth would result in potentially significant impacts. However, per federal, state and county regulations, many types of habitable structures (including homes, schools, etc.) are not allowed in 100-year floodplains. Compliance with these and a variety of other regulations and programs, as described below, would ensure that risks associated with development within 100-year flood hazard and other water hazard areas would be cumulatively less than significant.

Further, in terms of the GPU scenario, which accommodates the changes proposed by the project, Table 5.5-Q indicates that its incremental contributions *to development of the current General Plan within potential flooding areas* would be insubstantial (between *0-5%* ~~1-4%~~ at most) for the various development categories. Thus, the project's contribution to flooding risks would not be cumulatively considerable.

As detailed in Section 4.11.5, future development within Riverside County (regardless of scenario) also has the potential to incrementally introduce people, property, public facilities, roads and other infrastructure into areas potentially at risk of dam inundation or flooding due to other sources, e.g., failure of a levee or of a debris basin above an alluvial fan. As with 100-year floodplain effects, without measures that reduce flooding risks, this impact would be potentially cumulatively considerable. However, compliance with existing regulations and programs, as described below, would ensure that risks associated with development in dam inundation zones and other areas potentially prone to flooding or inundation hazards due to failure of a flood control facility are less than significant.

Drainage, Runoff and Hydrology Alterations: Future development would result in the incremental alteration of drainage patterns throughout Riverside County that would contribute to cumulative changes in drainage patterns, runoff and hydrological alternations. In addition to direct drainage alterations, temporary ponding or flooding could also result from development activities, reducing the water-carrying capacity of drainages, flood control facilities, storm drains, etc. Such drainage alterations and changes in runoff conditions must be reduced to prevent serious cumulative flooding risks.

Future development would also result in new land uses that would convert permeable surfaces (such as undisturbed soils and vacant lands) to impermeable surfaces, such as buildings (rooftops), parking lots and roadways. Increased impermeable surfaces would substantially alter the existing drainage patterns by incrementally increasing surface runoff, thereby increasing flooding hazards. Impermeable surfaces and development would also divert natural runoff patterns potentially resulting in flooding. Developed areas where much of the land surface is

covered by roads, buildings and other impermeable structures have little capacity to store rainfall. As a result of accelerated runoff from disturbed areas, peak discharge, volume and frequency of floods increases incrementally in nearby streams. To prevent this urban runoff from creating flood hazards, future development must be designed to direct and channel runoff appropriately into storm drain facilities adequately sized to handle expected flows. Such measures are, in fact, included as Conditions of Approval required for implementing projects; see regulatory compliance measures, below.

Seiche: Seiche, a standing wave in a completely or partially enclosed body of water, can in certain circumstances result in inundation (flooding) of areas located along the shoreline of a lake or reservoir. In Riverside County's semi-arid climate, naturally occurring enclosed water bodies are not common and none have documented seiche risks. For man-made water bodies, such as reservoirs, these are typically built by local municipalities or water districts to provide water service to local residents and businesses. Accordingly, most land around the reservoirs' shorelines is in public holdings, which restrict private land development and minimize risk of inundation from seiche. Moreover, such public land holdings are not within the jurisdiction of unincorporated Riverside County.

Mudflows and Debris Flows: Unincorporated Riverside County contains many areas with steep slopes and mountainous areas that could be subject to mudflows in the event of large amounts or precipitation. Narrow canyons, arroyos, alluvial fans and desert channels are also susceptible to flashfloods which can cause flooding damage directly or indirectly through mudflows. Areas of proposed land use-related changes with the potential for introducing or intensifying future development will contribute incrementally to increased exposure to mudflow hazards if they are: on or below a steep or unstable slope; within a steep-sided canyon; within an area with flashflood potential; on loose, unconsolidated soils; or in an area denuded of vegetation by recent wildfire, particularly if any of the other factors also occur. Flashflood potential generally exists along any canyon, swale or other low-lying area in which heavy precipitation fall may be channeled rapidly and unexpectedly. Risks to future development as a result of flashflood are minimized through the various regulatory floodplain and drainage flow control measures (as discussed under Impacts 4.11.A, 4.11.B and 4.11.C). In addition, site design and engineering requirements established for 100-year flood hazard management, e.g., under Riverside County Ordinance No. 458, generally provides sufficient measures to ensure the protection of development on alluvial fans.

c. Impacts

Future development accommodated will contribute incrementally to cumulative flooding and inundation impacts as Riverside County builds out over time pursuant to the Riverside County General Plan (regardless of scenario). With the regulatory and mitigation measures proposed (see below), cumulative impacts would be avoided, reduced or minimized to non-substantial levels. Specifically, these impacts will include the following:

- Encroachment into areas of mapped 100-year floods (including some alluvial fans) and other delineated flood hazards areas. Encroaching land uses would incrementally increase the people, structures and property at risk from a flooding event.

- Placement of structures within 100-year flood hazard areas to accommodate future growth can incrementally contribute to the impediment or redirection of flood flows. This could expose existing people, structures and property, as well as those introduced by new development, to increased flooding risks.

- Future development would incrementally increase the structures, including habitable ones, within dam inundation zones, alluvial fan flooding zones and other areas of potential flood hazard. Such development would be at greater risk of flood hazards should a dam, levee debris basin or other critical flood control structure fail.

- Development throughout Riverside County would incrementally alter drainage patterns, streams and river courses. It would also cumulatively increase surface runoff through the introduction of non-permeable surfaces (roofs, pavement, roads, etc.). If not properly managed, this would cause hydrological changes that could expose existing and new people, structures and property to increased flooding risks.

- Future development in areas subject to seiche have the potential to threaten people, structures and property. There is no documented significant potential for seiche in any of the waterbodies within Riverside County. Based on morphology and hydrology, however, two waterbodies in Riverside County (Lake Perris and Lake Elsinore) may have the potential for seismically induced seiche. Thus, future development downstream from or within the seiche flooding zones of these waterbodies may cumulatively increase the number of people and property potentially at risk. However, setbacks and flood hazard area regulations are expected to be sufficient protection against significant risks and thus future development along or near lakes and reservoirs is considered to be at minimal risk.

- Due to its inland location, by definition there are no tsunami risks, cumulative or otherwise, in Riverside County.

- Mudflow or debris flow can occur in areas with steep slopes, particularly areas with loose soils and/or denuded of vegetation (e.g., fire burn areas) when exposed to large amounts of precipitation, and narrow canyons, arroyos and desert channels are also susceptible to flashfloods which can cause flooding damage directly or indirectly through mudflows. Growth within Riverside County will incrementally increase the people and property potentially at risk for mudslide. However, when addressed through the required soil engineering, site design and maintenance, these risks can be maintained at less than significant.

d. Mitigation

As described in detail in Section 4.11.3, a variety of measures would be implemented to avoid, reduce and minimize adverse cumulative flooding and inundation impacts. These include the following:

(1) Regulatory Compliance

Key Regulations and Programs: See Section 4.11.3 for details on each regulation.

- FEMA Floodplain National Flood Insurance Program (see Ordinance No. 458)
- Federal Water Pollution Control Act of 1972 - Clean Water Act [CWA] Section 404
- National Pollution Discharge Elimination System (NPDES) per the CWA
- Cobey-Alquist Floodplain Management Act
- Ordinance No. 348 - Regulating Land Use
- Ordinance No. 457 - Adopting and Amending Various Building and Construction Codes
- Ordinance No. 458 - Regulating Flood Hazard Areas and Implementing the National Flood Insurance Program

- Ordinance No. 461 - Road Improvement Standards
- Ordinance No. 659 - Development Impact Fee (DIF) Program

Key General Plan Policies: See Section 4.11.3 for the text of each policy.

- Safety Element Policies: S 4.1-4.10, 4.12, 4.16-4.22

(2) CEQA Mitigation

The following CEQA mitigation measures were adopted as part of certification of EIR No. 441 for the RCIP General Plan in October 2003 and remain applicable to GPA No. 960 and future General Plan implementing projects:

- **Existing MM 4.9.1 A:** LOMA and LOMR-F are documents issued by FEMA that officially remove a property and/or structure from a special flood hazard area of a Flood Insurance Rate Maps (FIRM). These letters shall be accepted by Riverside County where applicable.
- **Existing MM 4.9.1 B:** Riverside County shall prohibit alteration of floodways and channelization unless alternative methods of flood risk management are found to be technically, economically and practicably infeasible.
- **Existing MM 4.9.1 C:** Riverside County shall not necessarily require all land uses to withstand flooding. These may include land uses such as agricultural, golf courses and trails. For these land uses, flows shall not be obstructed, and upstream and downstream properties shall not be adversely affected by increased velocities, erosion backwater effects, concentration of flows and adverse impacts to water quality from point and nonpoint sources of pollution.
- **Existing MM 4.9.1 D:** Riverside County shall require the 10-year flood flows to be contained within the top of curbs and the 100-year flood flows within the street rights-of-way.
- **Existing MM 4.9.2A:** Riverside County shall require that all structures (residential, commercial, and industrial) be flood-proofed from the 100-year storm flows. In some cases, this may involve elevating the finished floor more than one foot.
- **Existing MM 4.9.2B:** Riverside County shall require that fully enclosed areas that are below finished floors have openings to equalize the forces on both sides of the walls.
- **Existing MM 4.9.2C:** Riverside County shall require that for agricultural, recreation or other low-density uses, flows are not obstructed and that upstream and downstream properties are not adversely affected by increased velocities, erosion backwater effects, or concentration of flows.
- **Existing MM 4.9.2D:** Provided the applicant does hydrological studies, engineers structures to be safe from flooding and provides evidence that the structures will not adversely impact the floodplain, Riverside County may allow development into the floodway fringe.

e. Significance

Implementation of the above regulations, General Plan policies and mitigation measures would be sufficient to ensure that all of the incremental cumulative impacts listed above would be less than significant. As such, the project's incremental increase in exposure to flooding hazards would not be cumulatively considerable. In total, build out of any of the above General Plan scenarios would result in cumulatively considerable impacts due to flooding hazards, including dam inundation, seiche and mudflow.

11. Cumulative Effects on Geology and Soils

Section 4.12 (Geology and Soils) discusses existing geology, seismicity and soils within Riverside County and also analyzes geological and seismic hazards from future development. Areas already covered in Section 4.12 are not repeated here; see that section for additional details on sources and existing geological setting.

Section 4.12 of this EIR provides a complete description of geological and seismic hazards affecting Riverside County, as well as analysis of the existing and future seismic and geologic risks projected to occur as Riverside County builds out. This data includes Table 4.12-A (Probable Earthquake Scenarios), Table 4.12-B (General Liquefaction Potential Zones), Table 4.12-C (Geology Hazard Areas) and Table 4.12-D (Potential Project Areas Affected by Geological Hazard Areas). It also includes Figure 4.12.1 (Alquist-Priolo Fault Zones), Figure 4.12.2 (Earthquake Probability), Figure 4.12.3 (Liquefaction Zones), Figure 4.12.4 (Steep Slopes), Figure 4.12.5 (Documented Subsidence Areas), Figure 4.12.6 (Wind Erosion Susceptibility Areas) and Figure 4.12.7 (Near-Source Zone Regions, UBC Zone Boundary).

a. Existing Conditions

Seismic Hazards: A variety of geological hazards pose threats in Riverside County, particularly those associated with earthquakes. Seismic activity can cause hazards directly due to fault rupture and, more widely, ground-shaking. It can also cause liquefaction or subsidence of soils, rockfall, seiche and more. See Section 4.12.2 for full background on these hazards, including their relative likelihoods for occurrence in the various regions of Riverside County.

Earthquake risk is very high in the heavily populated western portion of Riverside County due to the presence of three of California's most active faults: the San Andreas, the San Jacinto and the Elsinore. Risk is moderate in the eastern portion of Riverside County which includes the Coachella Valley and Blythe. Riverside County is at risk from larger, more damaging earthquakes than the moderate sized, M_w 6.7 Northridge earthquake, which in 1994 caused 54 deaths and $20-$30 billion in damage.

Liquefaction Hazards: Liquefaction is a process by which water-saturated materials (including certain types of soil and sediment) lose strength and may fail during strong groundshaking, potentially resulting in one or more type of ground failure: lateral spread, flow failure, ground oscillation or loss of bearing strength. Areas of Riverside County with soil and hydrological conditions creating susceptibility for liquefaction hazards are depicted in Figure 4.12.3. Also, because there are several faults in Riverside County capable of generating peak ground accelerations of over 0.10 g (that is, acceleration with one-tenth the force of gravity), there is a high potential for seismically-induced rockfall and landslides to occur. Figure 4.12.1 shows areas of steep slopes within Riverside County, which are areas where rockfall hazards are greatest. In addition, Riverside County's valley regions containing relatively recent sediments may be susceptible to some degree of seismic settlement. The extent of relatively young sediments with moderate to locally high potential for settlement may be correlated with areas of valley fill represented on subsidence susceptibility mapping.

Ground subsidence can disrupt surface drainage, reduce aquifer system storage, form earth fissures and damage wells, buildings, roads and utility infrastructure. In addition to seismic sources, subsidence and fissuring have also been caused by falling groundwater tables and by hydrocollapse when groundwater tables rise in Riverside County. Figure 4.12.5 depicts areas of documented subsidence and other areas of Riverside County that may be susceptible to subsidence. Subsidence has been documented in three areas of Riverside County: the Elsinore Trough, including Temecula and Murrieta; the San Jacinto Valley from Hemet to Moreno Valley; and the southern Coachella Valley.

Wind Erosion Hazards: Much of Riverside County (approximately 20%) is vulnerable to high or very high wind erosion susceptibility. The Coachella Valley, the Santa Ana River channel and the Hemet region feature zones of high wind erosion susceptibility. See Figure 4.12.6 for wind erosion risks countywide. In particular, windblown sand is a well-recognized hazard for developments in the Coachella Valley. It has even forced abandonment of dwellings and subdivided tracts in the central Coachella Valley. The primary source of sand in the Coachella Valley is the Whitewater River.

Other Geological Hazards: In terms of soil erosion, topography and the length and steepness of slopes are crucial to determining the volume and velocity of runoff. As slope's length or steepness increases, the rate of runoff increases and the potential for erosion is magnified. Heavy or frequent rainfall also plays heavily into soil erosion hazards, particularly in post-burn areas where vegetation is absent.

b. Future Conditions

For future condition related to seismic and geological hazards, Tables 5.5-R, 5.5-S and 5.5-T, below, show cumulative conditions for the three General Plan build out scenarios examined in this section: Existing General Plan (CURR GP), the Updated General Plan as per GPA No. 960 (GPU/GPA960) and the cumulative General Plan as per the additional proposed GPAs through 2009 (CULM GP).

Seismic Hazards: Known and unknown fault zones criss-cross the County of Riverside. Future development within county fault hazard areas and state Alquist-Priolo earthquake fault hazard zones, would increase the potential for property loss, injury or death due to fault rupture. In terms of cumulative earthquake hazards, as measured by fault zone proximity (both county and Alquist-Priolo [state] fault zones), Table 5.5-R (Cumulative Fault Zone Effects) indicates that build out of the existing (current) General Plan will greatly increase (by nearly 200%) the amount of developed uses within the interface/wildland regions, with available open space and vacant land decreasing by nearly half (roughly *50,000* ~~48,000~~ acres). This is consistent with the conclusions in Section 4.12 that show wide swaths of Riverside County lie within regions with the potential for strong groundshaking hazards in the event of a major earthquake, as does much of Southern California.

For General Plan build out with the project (GPU/GP960 scenario), the data indicate that GPA No. 960's incremental contributions to new development within the fault zones will be negligible (under *5%* ~~3%~~ per development category) compared to that expected for the current General Plan. As such, the project's cumulative contribution to seismic hazards associated with fault rupture in Riverside County would be less than significant.

For the CULM scenario (build out of the General Plan assuming the project and all GPAs in process through 2009), incremental trends in development increasing in fault zones are generally similar to the GPU scenario. Development in fault zones would show slight incremental increases (*2-5%* ~~0-4%~~) for all categories ~~except for the Rural/Agricultural category, which would see roughly a 25% increase in development potential~~. However, these types of uses accommodate low residential densities and feature large amounts of open land (pastures, farmlands, etc.). In addition, in terms of acreage the incremental increase totals only about *1,900* ~~2,300~~ acres, which is less

than 1% of the total rural/agricultural area within unincorporated Riverside County. For this reason, the CULM scenario's incremental increase in seismic fault rupture hazards is not considered cumulatively considerable.

Table 5.5-R: Cumulative Fault Zone Effects

LAND USE SCENARIO	Urban/ Suburban	Rural/ Agriculture	Interface/ Wildlands	Vacant / Open Space	Public Facilities	Totals

Liquefaction Hazards: The cumulative effects of future development relative to potential liquefaction hazards are analyzed in Table 5.5-S (Cumulative Liquefaction Effects). The data indicate that build out of the current General Plan will continue the trend of development occurring in areas of high to very high liquefaction potential, as valley floors are favored growth areas and also contain sedimentary soils prone to liquefaction. Urban/suburban development in areas of high to very high liquefaction potential will nearly double under the CURR scenario and uses within interface/wildland areas will approach nearly 140% (a nearly 10,000-acre increase). These increases will be offset by decreased vacant/open space uses and also public facilities. Similar trends are reflected in areas of moderate, low and very low liquefaction potential.

For incremental impacts associated with the project, Table 5.5-S indicates that the with-project build out scenario (GPU/GPA960) would see a slight (*1%* ~~2%~~) reduction in development capacity within areas of high to very high liquefaction potential for both urban/suburban uses and rural/agricultural uses, *as compared to current General Plan build out* ~~as well as a 5% reduction in public facilities~~. These reductions are offset by a slight (*300-acre* ~~350-acre, 4%~~) increase for interface/wildland uses. All together, the incremental increase in liquefaction hazard potential associated with GPA No. 960 is negligible and not cumulatively considerable.

For the CULM scenario, however, the concentration on increasing urban/suburban development potential means this category would see an increase of nearly *1,600* ~~2,000~~ acres within the high to very high liquefaction hazard potential zones. This increase is offset by a *1,330-acre* ~~nearly 1,700 acre~~ reduction in acreage for rural/agricultural

lands within the same (high-very high) category. Interface/wildlands would see a slight (*2%* ~~3%~~, roughly 300-acre) increase and the remaining two categories would see negligible (30- to *150-acre* ~~300-acre~~) increases as well. There is a slight potential for the incremental urban/suburban increases in the high/very high category to be cumulatively considerable. However, adequate geoengineering techniques and requirements can avoid, reduce or minimize such impacts at the implementing project level to ensure they are not cumulatively significant. See mitigation discussion below.

2. Defined as the General Plan as of end of *2009* ~~2008~~.
3. *See Tables 11.1 through 11.4 in Appendix EIR-11 for more detailed data used in these tables.*

Source: Riverside County GIS *(RCIT)*, RCLIS layer (Liquefaction Potential Zones, updated as outlined in Section 4.12) and project application data, 2012 *and 2014*.

Wind Erosion Hazards: Lastly, growth pressure within Riverside County will result in development that causes the incremental loss, fragmentation and degeneration of areas of natural blowsand (such as sand dunes, for example) and sandy soils potentially prone to wind erosion regardless of the General Plan build out scenario. It will also result in potential incremental increases in windborne soil erosion when vegetation is removed and soils are disturbed as part of the c+onstruction process for buildings, roads and infrastructure.

The cumulative effects of future development relative to potential wind erosions hazards are analyzed in Table 5.5-T (Cumulative Wind Erosion Effects). Of all the build out scenarios, the table indicates that only under the current General Plan will there result in increased development (roughly *600* ~~1,000~~ acres) within areas of "very high" wind erosion potential. None of the other scenarios proposes additional development within "very high" hazard areas.

Within areas of "high" erosion potential, build out pursuant to the current General Plan will significantly increase the amount of disturbed areas in Riverside County. Specifically, urban/suburban development will increase over 80%, rural/agricultural uses will increase nearly 10% and development in interface/wildlands will increase nearly 225%. The amount of open and vacant acreage on "high" wind erosion potential soils will correspondingly decrease by 60%. Due to more accurate mapping, the amount of public facility uses within "high" hazard areas will decrease by roughly a third (by nearly 4,000 acres).

For build out of the General Plan with-project (GPU/GPA960 scenario), incremental changes to wind erosion hazards will be negligible. Both urban/suburban and rural/agricultural areas would decrease *very slightly* ~~by roughly 1% and p~~*P*ublic *F*~~f~~acility uses would *increase slightly (by 4%) as well* ~~decrease by nearly 10% (330 acres)~~. Within the interface/wildlands, development in "high" wind erosion hazard areas would increase by roughly 1% (roughly 1,200 acres). None of these changes are cumulatively considerable. The only large change for the GPU scenario is the roughly 3,200-acre increase in developed urban/suburban areas at "moderate" wind erosion risk. However, such an increase is not cumulatively significant since the soils' erosion potential can be adequately mitigated to less than significant levels through implementation of various mandatory regulatory and mitigation measures (see below). The CULM build out scenario shows trends similar to that of the GPU scenario. The incremental increases associated with the CULM scenario are similarly less than cumulatively significant.

Other Geological Hazards: For technical reasons (the sheer size of compiled topographic data that comprises Riverside County's steep slope data), it was not possible to perform a cumulative analysis for rockfall hazards. Section 4.12.6 provides a programmatic response for avoiding, reducing or minimizing rockfall hazards to the extent feasible. However, as outlined in Section 4.12.6, it cannot be ascertained at the countywide scale if such measures would be sufficient to fully reduce rockfall hazards to less than significant levels. For this reason, the project's incremental contributions to future development in areas potentially at risk for rockfall, mudslide and other slope-related geological hazards must be considered cumulatively considerable.

In terms of development on unstable geologic units and soils, as well as expansive soils, future growth may incrementally increase the potential for structure damage or interruption of utility service (through disruption of the facility). However, such impacts are not considered cumulatively considerable since the regulatory compliance measures identified below would ensure that impacts are avoided, reduce or minimized to less than significant levels. Cumulative impacts to subsurface sewer services would be similarly avoided, reduced or minimized to less than significant levels as well.

c. Impacts

Future development accommodated will contribute incrementally to cumulative geology and soil impacts as Riverside County builds out over time pursuant to the Riverside County General Plan (regardless of scenario). Specific impacts of the severities indicated will include the following:

(1) Cumulatively Considerable Impacts

- Like all of Southern California, Riverside County has experienced and will continue to face ground-shaking resulting from activity on local and regional faults. Thus, future development of any of the General Plan build out scenarios will incrementally increase the number of people and structures at risk of injury, death or property loss due to substantial strong seismic groundshaking.

- Landslides and rockfall can occur throughout Riverside County as a result of seismic activity and other natural processes, as well as resulting from human activity. Accordingly, future development of any of the General Plan build out scenarios will incrementally increase the number of people and structures at risk of injury, death or property loss due to substantial landslide or rockfall effects.

(2) Non-Substantial Incremental Impacts

For the risk outlined below, mandatory regulatory and/or mitigation measures (as listed below) will be sufficient to ensure adverse impacts are mitigated to cumulatively insignificant levels.

- Future development as the General Plan builds out (per any of the scenarios) will increase the potential for property loss, injury or death resulting from development where it occurs on or adjacent to known or as of yet undetected earthquake fault zones. This will incrementally expose people and structures to adverse effects due to rupture of a known earthquake fault. This risk, however, will be mitigated through compliance with various regulatory measures, including the prohibition on building on or adjacent to active faults.

- Portions of unincorporated Riverside County are susceptible to liquefaction, a destructive secondary effect of strong seismic shaking. This will incrementally expose people and structures to adverse effects due to seismic-related ground failure, including liquefaction.

- Areas potentially subject to soil erosion or topsoil loss will be incrementally exposed during future development activities as the General Plan (any scenario) builds out. Wind and water are the two biggest factors causing soil erosion, particularly where human activities have removed vegetation or otherwise disturbed the underlying soil.

- Unstable geological units and soils occur throughout Riverside County. Both natural and human activities have the potential to cause geologic instability. If improperly engineered or constructed, some

types of development, particularly those involving heavy loads (concrete dams, for example) or affecting subsurface water levels (e.g., groundwater pumping or replenishment facilities), have an increased potential to cause ground or soil failures. Accordingly, future development resulting from General Plan build out (of any scenario) would incrementally increase the potential for landslides, liquefaction, lateral spreading and subsidence as a result of placement on unstable geological units or soils.

- Expansive soils are widely distributed throughout Riverside County. Thus, any future development may incrementally increase the potential for the placement of structures and facilities in areas susceptible to damage resulting from expansive soils.

- Future development in areas outside of existing water and sewer service providers has the potentially to incrementally increase the number of structures and facilities in areas where soils are incapable of adequately supporting septic tanks or alternative wastewater disposal systems. Regulations are in-place to ensure this does not result in development on soils incapable of supporting septic tanks or other alternative wastewater disposal systems. (Development cannot be approved by the County of Riverside if sufficient waste disposal systems cannot be provided.)

d. Mitigation

As described in detail in Section 4.12.3, a variety of measures would be implemented to avoid, reduce and minimize adverse cumulative geological impacts. These include the following:

(1) Regulatory Compliance

Key Regulations and Programs: See Section 4.12.3 for details on each regulation.

- Federal Water Pollution Control Act of 1972 (Clean Water Act)
- California Building Standards Codes, Title 24, Section 1613
- California Building Standards Codes, Part 2, Chapters 18 and 18A (Soils and Foundations), Chapters 16 and 16A (Structural Design), and Chapters 17 and 17A (Structural Tests and Special Inspections)
- Riverside County Municipal Code Chapter 15.60 - Earthquake Fault Area Construction Regulations
- Ordinance No. 547 - Implementing the Alquist-Priolo Earthquake Fault Zoning Act
- Ordinance No. 484 - Blowing Sand Control

Key General Plan Policies: See Section 4.12.2 for the text of each policy.

- Safety Element Policies: S 2.1 - 2.8, 3.1 - 3.11, 3.13, 3.14, 7.7, 7.8, 7.11

(2) CEQA Mitigation

Existing Mitigation Measures (MMs): In EIR No. 441, which was certified for the 2003 RCIP General Plan, it was determined that mitigation would be necessary in order to reduce certain impacts associated with seismic

groundshaking, fault rupture, soil and wind erosion, and topsoil loss. The mitigation measures listed below are from EIR No. 441 and remain applicable to GPA No. 960 and future General Plan implementing projects.

- **Existing MM 4.10.1A:** Before a project is approved or otherwise permitted within an Alquist-Priolo Zone, County Fault Zone, within 150 feet of any other active or potentially active fault mapped in a published United States Geologic Survey (USGS) or CGS reports, or within other potential earthquake hazard area (as determined by the [Riverside] County Geologist), a site-specific geologic investigation shall be prepared to assess potential seismic hazards resulting from development of the project site. The site-specific geotechnical investigation shall incorporate up-to-date data from government and non-government sources.

  Based on the site-specific geotechnical investigation, no structures intended for human occupancy shall be constructed across active faults. This site-specific evaluation and written report shall be prepared by a licensed geologist and shall be submitted to the [Riverside] County Geologist for review and approval prior to the issuance of building permits. If an active fault is discovered, any structure intended for human occupancy shall be set back at least 50 feet from the fault. A larger or smaller setback may be established if such a setback is supported by adequate evidence presented to and accepted by the [Riverside] County Geologist.

- **Existing MM 4.10.2A:** The design and construction of structures and facilities shall adhere to the standards and requirement detailed in the California Building Code (California Code of Regulations, Title 24), [Riverside] County Building Code, and/or professional engineering standards appropriate for the seismic zone in which such construction may occur. Conformance with these design standards shall be enforced through building plan review and approval by the Riverside County Department of Building and Safety prior to the issuance of building permits for any structure or facility.

- **Existing MM 4.10.2B:** As determined by the [Riverside] County Geologist, a site-specific assessment shall be prepared to ascertain potential groundshaking impacts resulting from development. The site-specific groundshaking assessment shall incorporate up-to-date data from government and non-government sources and may be included as part of any site-specific geotechnical investigation required in [existing EIR No. 441] Mitigation Measure 4.10.1A. The site-specific groundshaking assessment shall include specific measures to reduce the significance of potential groundshaking hazards. This site-specific groundshaking assessment shall be prepared by a licensed geologist and shall be submitted to the [Riverside] County Geologist for review and approval prior to the issuance of building permits.

- **Existing MM 4.10.2C:** The standards stated in [existing EIR No. 441] Mitigation Measures 4.10.2A and 4.10.2B shall apply to any structure of facility that undergoes expansion, remodeling, renovation, refurbishment or other modification.

- **Existing MM 4.10.3A:** As determined by the [Riverside] County Geologist, a site-specific assessment shall be prepared to ascertain potential liquefaction impacts resulting from development. The site-specific liquefaction assessment shall incorporate up-to-date data from government and non-government sources and may be included as part of any site-specific geotechnical investigation required in [existing EIR No. 441] Mitigation Measure 4.10.1A. This site-specific groundshaking assessment shall be prepared by a licensed geologist and shall be submitted to the [Riverside] County Geologist for review and approval prior to the issuance of building permits.

- **Existing MM 4.10.3B:** Where development is proposed within an identified or potential liquefaction hazard area (as determined by the [Riverside] County Geologist), adequate and appropriate measures such

as (but not limited to) design foundations in a manner that limits the effects of liquefaction, the placement of an engineered fill with low liquefaction potential, and the alternative siting of structures in areas with a lower liquefaction risk, shall be implemented to reduce potential liquefaction hazards. Any such measures shall be submitted to the Riverside County Geologist and the [Riverside] County Department of Building and Safety for review prior to the approval of the building permits.

- **Existing MM 4.10.7A:** Proponents of new development within Riverside County shall adhere to applicable policies and standards contained in the most recent version of the [California] Building Code related to the construction of structures and facilities on expansive soils.

- **Existing MM 4.10.8A:** New development within identified or potential (as determined by the [Riverside] County Geologist) wind hazard areas shall adhere to applicable provisions of Riverside County Ordinance No. 484.2 or other local, state, or federal requirements established to control or limit the windborne erosion of soil. Prior to the approval of development permits, the [Riverside] County Building and Safety Department shall confirm that the design of any proposed structure, facility, or use incorporates appropriate features to control and/or limit the windborne erosion of soil.

- **Existing MM 4.10.9A:** Riverside County, where required, and in accordance with issuance of a National Pollutant Discharge Elimination System (NPDES) permit, shall require the construction and/or grading contractor for individual developments to establish and implement specific Best Management Practices (BMPs) at time of project implementation.

- **Existing MM 4.10.9B:** Prior to any development within the county, a Grading Plan shall be submitted to the Riverside County Building and Safety Department and/or Riverside County Geologist for review and approval. As required by the County [of Riverside], the grading plan shall include erosion and sediment control plans. Measures included in individual erosion control plans may include, but shall not be limited to, the following:

  a. Grading and development plans shall be designed in a manner which minimizes the amount of terrain modification.

  b. Surface water shall be controlled and diverted around potential landslide areas to prevent erosion and saturation of slopes.

  c. Structures shall not be sited on or below identified landslides unless slides are stabilized.

  d. The extent and duration of ground disturbing activities during and immediately following periods of rain shall be limited, to avoid the potential for erosion which may be accelerated by rainfall on exposed soils.

  e. To the extent possible, the amount of cut and fill shall be balanced.

  f. The amount of water entering and exiting a graded site shall be limited though the placement of interceptor trenches or other erosion control devices.

  g. Erosion and sediment control plans shall be submitted to the County [of Riverside] for review and approval prior to the issuance of grading permits.

- **Existing MM 4.10.9C:** Where required, drainage design measures shall be incorporated into the final design of individual projects on site. These measures shall include, but will not be limited to:

  a. Runoff entering developing areas shall be collected into surface and subsurface drains for removal to nearby drainages.

  b. Runoff generated above steep slopes or poorly vegetated areas shall be captured and conveyed to nearby drainages.

  c. Runoff generated on paved or covered areas shall be conveyed via swales and drains to natural drainage courses.

  d. Disturbed areas that have been identified as highly erosive shall be (re)vegetated.

  e. Irrigation systems shall be designed, installed and maintained in a manner which minimizes runoff.

  f. The landscape scheme within the project site shall utilize drought-tolerant plants.

  g. Erosion control devices such as rip-rap, gabions, small check dams, etc., may be utilized in gullies and active stream channels to reduce erosion.

e. Significance

The analysis above indicates that future development consistent with any of the General Plan build out analyzed, including the proposed project (GPA No. 960), would contribute mostly non-substantially to incremental impacts related to geology, seismicity and soils. Implementation of existing regulations, General Plan policies and CEQA mitigation measures would reduce potential incremental effects of fault rupture hazards, groundshaking, liquefaction, landslides and rockfall, seismically induced settlement, subsidence and collapsible soils, soil erosion and loss of topsoil are either avoided or minimized to less than significant levels. Compliance with existing laws would also ensure structures, people and property are protected from cumulative geologic hazards through engineering designed according to the applicable seismic and geological risks or that development is not permitted where such risks are excessive (i.e., higher than typical for the given area or geology) and cannot be avoided.

However, even with mitigation, the project would contribute substantially to significant cumulative impacts stemming from growth leading to the potential exposure of additional people and structures to substantial strong seismic groundshaking and also to substantial adverse effects due to landslide or rockfall. Build out of the cumulative General Plan scenario would do likewise. Due to the inherently growth-inducing and growth-accommodating nature of a General Plan, there is no feasible mitigation that will fully reduce these cumulative impacts to below the level of significance, although mitigation to address these hazards is included herein. Thus, even though project effects would be individually limited, GPA No. 960's incremental contribution to cumulative groundshaking and landslide/rockfall hazards would be significant and unavoidable.

12. Cumulative Effects on Hazardous Materials and Safety

Section 4.13 (Hazardous Materials and Safety) discusses existing risks from hazardous materials, wildfires, air travel and other hazards in Riverside County, as well as the sources and updates used. It also analyzes safety hazards from future development accommodated by the project, GPA No. 960, as well as the mitigation (through

regulatory compliance) necessary to ensure impacts are less than significant. Areas already covered in Section 4.13 are not repeated here; see that section directly for additional resource details.

Section 4.13 provides a complete description of the safety hazards and hazardous material risks affecting Riverside County, as well as analysis of the existing and future risks projected to occur as Riverside County builds out. This data includes Table 4.13-A (Major Hazardous Material Sites in Riverside County), Table 4.13-B (Airport Compatibility Zone Safety and Airspace Protection Factors), Table 4.13-C (Air Facilities In and Around Riverside County), Table 4.13-D (Largest Fires in California Over the Past Decade), Table 4.13-E (California State Jurisdiction Wildfire Statistics for 2000-2010), Table 4.13-F (Housing Density Classes for Defining Types of Fire Hazard Lands) and Table 4.13-G (Minimum Fire Protection Flows).

It also includes Figure 4.13.1 (Location of Major Hazardous Materials Sites), Figure 4.13.2 (Location of Public Airports), Figure 4.13.3 (Military Airspace Over Riverside County), Figure 4.13.4 (Military Training Airspace and Training Routes Over Riverside County), Figure 4.13.5 (Weapon, Laser and Surface Danger Safety Zones at CMAGR), Figure 4.13.6 (Fire Responsibility Areas) and Figure 4.13.7 (Fire Hazard Severity Zones).

a. Existing Conditions

Hazardous Materials: Federal and state databases indicate 36 major sites of hazmat contamination in Riverside County; i.e., federal Superfund or National Priorities List (NPL), State Response or Cortese List sites. See Figure 4.13.1 and Table 4.13-A for locations and descriptions for each of these major sites. By category, Riverside County contains four "Superfund" or federally listed hazmat sites, 26 "State Response" sites and 19 contaminated sites on the "Cortese List" (some of these sites overlap lists). In addition, information from the Riverside County Department of Environmental Health (DEH) and Planning Department indicates there are nearly 9,000 individual sites in Riverside County permitted to transport, generate, handle or dispose of hazardous materials. According to state records, there are also 15 voluntary cleanup sites, 14 school cleanup sites, 12 corrective action sites and 21 tiered-permit sites, although some of these include the 36 sites identified above.

See Section 4.13 for more information on all of the various sources of existing hazardous materials and sites of potential contamination, such as LUSTs (Leaking Underground Storage Tanks) tracked by the State of California, hazardous waste generators (which also require permits from the state) and military sites (home to both past contaminations and current/on-going use of hazardous materials, particularly fuels and other petroleum products). For military sites, including closed facilities, the most significant hazardous material potentially found on or near these facilities is unexploded ordnance (e.g., bombs). Major medical facilities in Riverside County, such as Riverside County Regional Medical Center and over 20 others, also generate a variety of hazardous substances in the form of "medical wastes," which may also be biohazardous.

There are currently seven active landfills within the unincorporated Riverside County; six operated by the Riverside County Waste Management Department and one (El Sobrante) privately owned and operated. All of the landfills currently located in Riverside County are Class III landfills and accept only nonhazardous solid waste. Hazardous waste generated within Riverside County must be disposed of in Kern County or Santa Barbara County, which have active Class I landfills.

Rail and highway transportation routes, and the varied industries that use them, create the potential for hazardous materials incidents within Riverside County. Although incidents can happen almost anywhere, certain areas of Riverside County are at higher risk for inadvertent release of hazardous materials. Locations near freeways and roadways that are frequently used for transporting hazardous materials (e.g., SR-91, I-15) and locations near industrial facilities that use, store or dispose of these materials all have an increased potential for a release incident, as do locations along the county's freight railways. The amount of hazardous materials transported over

county roadways on a daily basis is unknown, but is estimated to be steadily increasing due to the growth of overall traffic and industry in Riverside County. In addition to the accidental release of gasoline, diesel, oil and other automotive products during vehicle collisions, the transport of hazardous materials on highways within Riverside County presents a risk of upset and/or release of these substances.

There are also many rail lines running through Riverside County, which often carry hazardous cargoes. Major rail lines which cross Riverside County are shown in Section 4.18 (Transportation and Traffic). The most common hazardous material incidents involving rail transport are due to train wrecks and derailments. And, not to be overlooked as a potential source of hazardous materials, particularly petroleum-based ones, are Riverside County's public airports and private fields and airstrips. Even with stringent federal regulations on hazardous materials, accidents still occur. The types of incidents most commonly occurring at airports in Riverside County are illegal disposal of hazardous materials, fuel spills and leaking underground storage tanks; that is, activities related to aircraft and airport maintenance, rather than air transport.

Riverside County is also home to an extensive network of pipeline distribution systems, including a jet fuel (JP-8) line and three high-pressure natural gas transmission pipelines. All areas with natural gas pipelines are at risk for potential pipeline failure and gas-release hazards. Petroleum products are also stored and distributed at many major points throughout Riverside County.

Airports and Aircraft Hazards: Hazards associated with air travel, such as accidents and mishaps during flight can technically occur at any point along a plane's flight path, which can span thousands of miles. The locations most likely to experience air hazards are those closest to airport runways because statistically takeoff and landing are the most common points of mishap during air flight. Airport master plans and airport land use compatibility plans are designed to keep people and property out of the most dangerous portions of the runways and ensure that land uses permitted in proximity to the airport are compatible with the air hazards.

The western part of Riverside County has some of the busiest air traffic in the United States, including very heavy commercial, as well as military, air traffic. The airspace in Riverside County is constantly occupied by aircraft arriving and departing from other airports in the region. The number of near misses reported by pilots underscores the increasing possibility of a mid-air collision over Riverside County. Accordingly, the use of airspace and aircraft overflight represents a remote hazard to many portions of Riverside County. There are also two major airports in Riverside County, March Joint Air Reserve Base (MARB) and Palm Springs International, a military air bombing range (the Chocolate Mountain Aerial Gunnery Range), 13 smaller public commercial airports and dozens of private airstrips; see Table 4.13-C.

A variety of military airspace uses can lead to conflicts between military and civilian aircraft if an error is made by one or more pilots, mechanical failure, etc. As a result, there is a very small risk of accident for the thousands of people and properties on the ground below these routes. To prevent conflicts, MOAs ("military operations areas") segregate certain non-hazardous military activities from civilian and commercial air traffic. Areas above military bases, near actual combat or other military emergencies are generally designated as "restricted airspace." MOAs in Southern California, including portions of eastern Riverside County, are shown in Figure 4.13.3 and a number of "military training routes" (MTRs), which link the various facilities of the Bob Stump Complex, as well as providing routes across the country and overlie Riverside County are shown in Figure 4.13.4.

Wildland Fire Hazards: In California, wildfire and, in particular, wildland-urban interface fires, represent the third-most destructive source of hazard, vulnerability and risk. As people and development encroach further into wildlands, these fire risks increase. In addition, increasingly dry years due to climate change, plus insect predation and other factors led to record amounts of dead and dying vegetation accumulating in the state's wildlands, further exacerbating fire hazards. As the urban environment extends into open areas, fires in wildland-urban

interfaces present unique challenges due to the complex mixture of fuels, properties and threats. According to the California Multi-Hazard Mitigation Plan (MHMP), California experiences an average of 5,000 wildland/urban interface (WUI) fires each year.

Compared to historic fire regimes, many mixed-conifer forests in California now experience more intense and severe fires. The state's chaparral shrublands also now burn more frequently. Both trends can be traced back to the prior century of fire exclusion and rigorous suppression, which has led to these altered regimes. This trend is particularly acute in Southern California where burgeoning population growth in fire-prone areas has resulted in increased ignitions through accident or arson. As a result, this has contributed to the conversion of much of the original sage scrub habitats, particularly in flatlands and low hills, to non-native grasslands and ruderal (weedy) fields. Overall, much of Riverside County is considered to have a moderate to high potential for wildland fires according to CalFire. See Section 4.13.3 for details on each of the habitat types and their relative fire hazards for Riverside County.

To ensure adequate coverage across numerous jurisdictions, the state organizes lands into three basic categories according to the agency fiscally responsible for fire response: Federal Responsibility Areas (FRAs), State Responsibility Areas (SRAs) and Local Responsibility Areas (LRAs). See Section 4.13.3.C for specifics on each. As shown in Figure 4.13.6, in Riverside County SRAs (under CalFire jurisdiction) comprise the largest portion of unincorporated territory, over 544,000 acres. LRAs under CalFire are associated mostly with the cities (plus over 13,000 acres in unincorporated areas), and there are large swaths of FRAs within Riverside County as well (nearly 53,000 acres under BLM jurisdiction and over 62,000 acres under the U.S. Forest Service).

CalFire also designates fire hazard severity zones (FHSZs), which are "geographical areas classified as Very High, High or Moderate in State Responsibility Zones or as Local Agency Very High Fire Hazard Severity Zones" pursuant to the California Fire Code. These zones are used to determine the appropriate construction materials for new buildings within WUI areas. Specifically, the regulations of the California Building Code (CBC) Chapter 7A (as amended via County Ordinance No. 787) are mandatory in SRA FHSZs and LRA very high FHSZ areas. Much of the hilly portions of unincorporated Riverside County have substantial fire risks and are designated as SRAs with moderate, high or very high fire hazard. See Figure 4.13.7.

The County of Riverside contracts with the State of California (i.e., CalFire) for fire protection. Under CalFire management, the Riverside County Fire Department (RCOFD) operates 95 fire stations in 17 battalions. Fifty-one of these stations, as well as three stations operated directly by CalFire, are located in the unincorporated portion of Riverside County (see Table 4.17.2-A in Section 4.17.2 for full details).

b. Future Conditions

Table 5.5-U (Cumulative Fire Responsibility Area Effects), below, shows the cumulative conditions for the three General Plan build out scenarios examined in this section: Existing General Plan (CURR GP), the Updated General Plan as per GPA No. 960 (GP/GPA960) and the cumulative General Plan as per the additional proposed GPAs through 2009 (CULM GP). Only cumulative fire hazards are examined quantitatively. The spatial data associated with the other types of hazards in this section, most notably hazardous materials and air hazards, do not readily lend themselves to this type of analysis. They are instead approached programmatically for cumulative impacts within Riverside County.

Hazardous Materials: With the extensive distribution of hazmat sites throughout Riverside County, some of the future development will occur near sites or facilities where hazardous materials are present, regardless of the General Plan build out scenario. However, due to prohibitions on development (and/or strict remediation

requirements) for contaminated sites, the incremental effects would not be cumulatively considerable for any of the scenarios.

Effects from the accidental release of a hazardous material into the environment could have serious consequences on the environment, property and human health depending upon the size, location, type and quantity of the release. However, hazardous material uses, siting, transport and disposal are subject to extensive federal and state regulation and permit requirements. These measures ensure that risks are minimized, regardless of location. Thus, build out of Riverside County, regardless of General Plan scenario, would not result in cumulatively considerable hazardous material effects due to accidental release.

Airports and Aircraft Hazards: For any of the General Plan build out scenarios, population growth in Riverside County would create incremental increases in demand for air transportation. At the same time, growth and urbanization would also introduce incompatible land uses, people and property into airports' vicinities. To ensure incremental effects of encroachment on existing and future air operations are not cumulatively significant, the State Aeronautics Act (Public Utilities Code section 21670 *et seq.*) requires the adoption of airport land use compatibility plans by the Riverside County Airport Land Use Commission (ALUC). These plans ensure that existing and future land uses planned around public use airports are compatible and safe through a variety of limits, restrictions (e.g., on building heights, hazardous material use or storage, sensitive uses, etc.) and other land use requirements.

Wildland Fire Hazards: Future development occurring as the General Plan builds out will result in an increase in the people, property and infrastructure needing fire protection and potentially at risk of wildfire threat. The data in Table 5.5-U show the cumulative effects of scenario build out on the various Fire Responsibility Areas within Riverside County. In addition to reflecting increased uses exposed to fire hazards, the future uses indicated also reflect the amount of increased demand for (and wear-and-tear on) the various fire agencies, equipment and personnel providing the needed fire services. See Section 4.17.2 (Public Services - Fire Protection) for specifics on fire departments, staffing, etc., and Section 5.5.16 for cumulative effects on fire services.

Per Table 5.5-U, growth pressures within Riverside County will result in increased urban, suburban and rural development. Under the existing General Plan (CURR GP scenario), build out will greatly increase the amount of developed uses within the State Responsibility Area (SRA); from roughly 150,000 acres to over *500,000* ~~520,000~~ acres. Interface/wildland areas, typically at greatest risk for wildfires due to adjacent and interspersed open vegetation, account for nearly 350,000 acres of this increase alone. Similar increases would also occur within Local Responsibility Areas as well under the CURR GP scenario. As such, build out of the existing General Plan (CRR GP) would result in cumulatively considerable increases wildfire hazards within Riverside County.

Build out according to the General Plan with GPA No. 960 (i.e., the GPU/GPA960 scenario) would reduce the amount of developed uses allowed within interface/wildland areas (by over 15,000 acres) and increase the amount of vacant and open space land. These changes, however, would be offset by increased development of urban/suburban and public facility uses in SRAs and LRAs. The incremental contributions of each of these increases are individually minor. However, given the significant wildland fire hazards already associated with General Plan build out, even these increases would be cumulatively considerable.

For the CULM scenario (General Plan plus proposed GPAs), both SRAs and LRAs would see even greater increases in developed uses. This is particularly true of rural/agricultural uses in SRAs and urban/suburban uses in LRAs. Interface/wildland uses would actually decrease under the CULM scenario. However, nearly all of the acreage decreased would instead be converted to urban/ suburban or rural/agricultural uses and thus would substantially reduce cumulative impacts. Thus, overall, the CULM General Plan build out scenario would also result in incremental increases in fire hazard potential that are individually minor but cumulatively considerable.

c. Impacts

Future development will contribute incrementally to cumulative impacts related to hazardous materials, wildfires, air travel and other safety hazards as Riverside County builds out over time pursuant to the County General Plan (regardless of scenario). Specific impacts of the severities indicated will include the following:

(1) Cumulatively Considerable Impacts

- Build out of Riverside County would result in development in previously undisturbed areas, including some with high or very-high fire hazards, particularly rural mountainous areas. This would increase the people, property and structures potentially exposed to wildland fire hazards, particularly within the expanding urban-wildland interface areas within Riverside County. Additionally, there is the potential for an increase in the occurrence of fires, particularly in urban-wildland interface areas, due to increasing human encroachment. See discussion under Impact 4.13.H. The incremental effect of growth within Riverside County would result in cumulatively considerable fire hazard increases regardless of the General Plan build out scenario, including the future growth associated with the project, GPA No. 960.

(2) Non-Substantial Incremental Impacts

- Future development would introduce more people, property and structures to potential hazards as a result of the routine transport, use or disposal of hazardous materials, for example through toxic spills or other contamination events.

- Growth would increase the use, transport and disposal of hazardous substances, increasing the risk of accidental release of hazardous materials, e.g., during transport or through accidental explosion or other accidental means.

- Future development would also increase the potential for hazardous emissions or related hazards within one-quarter mile of a school; both by increasing use of hazardous substances near existing schools and by introducing new schools potentially into proximity of hazardous materials.

- Similarly, future development would also increase the potential for hazards due to development on or near a site on the State of California's Cortese List of contaminated sites, leaking underground storage tanks, hazardous waste sites, etc.

- Future development would introduce more people, property and structures to potential hazards as a result of their proximity (generally within 2 miles) to public use airports, as well as private air facilities, heliports, military air bases, etc.

- Future development would result in more people and their vehicles needing to evacuate an area in the event of an emergency, particularly for wildfires. This additional traffic could hinder emergency response plans for public safety personnel and equipment in a disaster or emergency.

d. Mitigation

As described in detail in Section 4.13.3, a variety of measures would be implemented to avoid, reduce and minimize adverse cumulative hazardous material and safety impacts. These include the following:

(1) Regulatory Compliance

Key Regulations and Programs: See Section 4.13.3 for details on each regulation.

- Comprehensive Environmental Response, Compensation and Liability Act

- Resource Conservation and Recovery Act
- Hazardous Materials Transportation Act
- California Emergency Services Act
- Statewide Standardized Emergency Management System
- Hazardous Waste Control Law
- Riverside County Fire Protection Master Plan
- Ordinance No. 269 – Height Limits of Structures within Certain Distances of March Field
- Ordinance No. 348 - Regulating Land Use
- Ordinance No. 448 - Airport Operations
- Ordinance No. 576 - Regulating County Airports
- Ordinance No. 615 – Hazardous Waste Storage, Treatment and Recycling
- Ordinance No. 617 – Underground Storage Tanks Containing Hazardous Substances
- Ordinance No. 651 – Disclosure of Hazardous Materials and Emergency Response
- Ordinance No. 695 - Abatement and Notices for Hazardous Vegetation
- Ordinance No. 718 - Regulating Medical Wastes
- Ordinance No. 787 - Fire Code Standards

Key General Plan Policies: See Section 4.13.3 for the text of each policy.

- Safety Policies: S 5.1 - 5.21, 6.1, 7.1 - 7.3, 7.6, 7.9 and 7.14
- Land Use Policies: LU 1.8, 5.1, 7.8, 7.9, 10.1, 15.1 - 15.9 and 31.2

e. Significance

The analysis above indicates that future development consistent with any of the General Plan build out scenarios analyzed, including the proposed project (GPA No. 960), would contribute mostly non-substantially to incremental impacts related to hazardous materials and safety issues. Non-substantial cumulative impacts associated with GPA No. 960 include: use, storage and transport of hazardous materials, accidental release of hazardous materials, hazardous emissions near schools and effects from existing site contamination, as well as safety hazards for people within two miles of a public or public-use airport, private airstrip or heliport.

Even with mitigation, however, the project would contribute substantially to significant cumulative impacts due to increased people and property in areas at risk for high or very high fire hazards, particularly within interface/

wildland areas. Build out of the cumulative General Plan scenario would do likewise. Due to the vast expanse covered by Riverside County, the wide variety of potential fire sources and fuels, and the sheer number of people and properties involved, even with the reduction of individual implementing projects to less than significant levels, the wildfire risk within Riverside County overall would remain cumulatively considerable for all of the General Plan build out scenarios. There is no feasible mitigation that would fully reduce these cumulative impacts to below the level of significance. Thus, even though project effects would be individually limited, GPA No. 960's incremental contribution to cumulative housing and population impacts would be significant and unavoidable. Build out of the cumulative General Plan scenario would also result in significant and unavoidable cumulative impacts to population and housing within Riverside County.

13. Cumulative Effects on Mineral Resources

Section 4.14 (Mineral Resources) discusses existing mineral resources in Riverside County, as well as the sources (and any updates) used. It also analyzes impacts from future development accommodated by the project, GPA No. 960, as well as the mitigation (through regulatory compliance) that would ensure impacts are less than significant. Areas already covered in Section 4.14 are not repeated here.

Section 4.14 of this EIR provides a complete description of the mineral resources and industry in Riverside County, as well as analysis of the existing and future impacts projected to occur as the county builds out. This data includes Table 4.14-A (Changes Affecting State Mineral Resource Areas) and Figure 4.14.1 (Mineral Resource Areas in Riverside County), Figure 4.14.2 (Riverside County Aggregate Resources of the Temescal Valley-Orange County and San Bernardino Production-Consumption Regions) and Figure 4.14.3 (Aggregate Resources of the Palm Springs Production-Consumption Region).

a. Existing Conditions

In Riverside County, most of the economically valuable mineral deposits known to occur in the county are located along Interstates 15, 215 and 10. Industrial minerals occurring and extracted in Riverside County currently include: clay, limestone, sand and gravel ("aggregates"), specialty sands and rock commodities. See Section 4.14.2 for specifics on the mineral commodities, locations and estimated amounts occurring in Riverside County.

The State Mining and Geology Board (SMGB) uses "Mineral Resource Zones" (MRZs) to classify lands that contain valuable mineral deposits. Use of MRZs can help identify mineral deposits to be protected from encroaching urbanization and land uses incompatible with mining. *The footnotes in Table 5.5-V provides descriptions of each of the MRZs.* After an area has been classified into MRZs, the SMGB then determines if the "classified" mineral resource deposit warrants "designation" as being of either "regional" (multi-community) or "statewide economic significance." Figure 4.14.1 in Section 4.14 identifies the areas within Riverside County with potential mineral resource deposits, according to State of California MRZ classifications. There are no sites within Riverside County designated as "locally important mineral recovery sites."

In defining economic viability, the State of California uses large, multi-county "Production-Consumption Regions" as their boundaries for study areas for aggregate production and their associated market areas. Figures 4.14.2 and 4.14.3 in Section 4.14 show the production-consumption regions occurring in Riverside County. See Section 4.14.3 for specifics on each region.

b. Future Conditions

Table 5.5-V (Cumulative Mineral Resource Zone Effects), below, shows the cumulative conditions for the three General Plan build out scenarios examined in this section: Existing General Plan (CURR GP), the Updated General Plan as per GPA No. 960 (GP/GPA960) and the cumulative General Plan as per the additional proposed GPAs through 2009 (CULM GP).

It should be noted that, as shown in Figure 4.14.1 in Section 4.14, the Riverside County General Plan does not contain any "locally important mineral resource recovery sites." Since GPA No. 960 does not propose to change this, the proposed project would not have an effect on this type of resource. Similarly, build out of the CULM scenario would likewise have no effect as well.

Footnotes:

1. Mineral Resource Zone (MRZ) classifications as established by the State Mining and Geology Board (SMGB):
   MRZ-1: Available geologic information indicates no significant mineral deposits present or there is little likelihood for their presence.
   MRZ-2: Available geologic information indicates significant measured (MRZ-2a) or inferred (MRZ-2b) mineral deposits present.
   MRZ-2 in Sectors: "Sectors" are MRZ-2 areas identified by SMGB as having "significant aggregate resources."
   MRZ-3: Available geologic information indicates existing mineral deposits of undetermined significance, with moderate potential for economic viability (MRZ-3a) or inferred viability (MRZ-3b).
   MRZ-4: Areas where not enough information is available to determine presence/absence of mineral deposits.
   Unstudied: Areas not studied by the SMGB.
   For more details on MRZ categories, see Section 4.14.2.B.
2. Defined as the General Plan as of end of *2009* ~~2008~~.
3. *See Tables 14.1 through 14.4 in Appendix EIR-11 for more detailed data used.*

Source: Riverside County GIS *(RCIT)*, RCLIS layer (Mineral Resource Zones, updated per SMGB data, as outlined in Section 4.14) and project application data, 2012 *and 2014*.

As indicated in Table 5.5-V, build out of the current (*2009* ~~2008~~) General Plan will result in incremental increases in the amount of MRZ-2 *(significant mineral deposits known or inferred present)* land lost to urban/suburban and rural/agricultural development, including to a lesser degree land within Sectors (that is, significant aggregate resources). Larger amounts of both MRZ-2 and Sectors will also be converted from vacant/open space to interface/wildland uses. MRZ-4 areas *(areas without enough information)* will see similar incremental conversions. In these areas, build out would contribute incrementally to loss of potentially valuable mineral resources in Riverside County.

For the General Plan scenario that includes the proposed project (i.e., the GPU/GPA960 scenario), incremental growth accommodated by the project would have a negligible (plus or minus ~~less than~~ 50 acres *or less*) effect on MRZ-2 and Sectors within any development category. *The biggest area of change caused by project (GPU) buildout would be the loss of nearly 7,500 acres of "unstudied" lands within currently vacant areas and open space. This loss would potentially be offset by a reduction in development footprint of over 9,300 acres of "unstudied" lands in the interface and wildlands of Riverside County. This may mitigate the adverse effects. However, without additional information the extent of any mitigation value cannot be predicted. The overall net effect, at any rate, indicates that General Plan buildout with the project would result in over 1,400 fewer acres of "unstudied" areas affected by future development.* ~~Incremental effects on MRZ-4 areas will also be minimal, as the largest area of loss would only be 2% of the total (for 150 acres of additional public facility uses). Unstudied areas would be similarly affected, with losses of 2% (under 200 acres) due to new urban/suburban uses and 4% (110 acres) of additional vacant/open space area lost. Areas of undetermined significance (MRZ-3) would be similarly~~

~~affected, with the greatest incremental losses totaling 4% due to additional urban/suburban uses and public facilities; that is, 3,100 acres and 610 acres, respectively.~~ None of these losses, however, would have a cumulatively considerable effect on mineral resource availability, including aggregates.

For build out of the CULM scenario, similar trends for MRZ-2 and Sectors are observed. Table 5.5-V also indicates that this scenario would have *a minor cumulative loss* ~~somewhat greater cumulatively losses~~ of mineral resources due to ~~larger~~ increases in urban/suburban areas. Growth in these areas would *also slightly* increase losses of unstudied and MRZ-4 areas *as well* ~~by an additional 40-50% (3,900 acres and 2,300 acres, respectively)~~. These losses are not likely to be cumulatively considerable, however, because of the large inventory of vacant land (roughly 1.3 million acres) that would remain available for potential mineral resource utilization under the CULM scenario even at full build out.

c. Impacts

Future development will contribute incrementally to cumulative mineral resource and mining impacts as Riverside County builds out over time pursuant to the Riverside County General Plan (regardless of scenario). Specific impacts will include the following:

- Future development pursuant to any of the General Plan build out scenarios, including that with the project, will contribute incrementally, but not significantly, to the loss of availability of known mineral resources that would be of value to the region and the residents of the State of California, including within Sectors containing significant aggregate resources.

- Future development would also contribute incrementally, but not significantly, to the loss of lands where the availability and/or economic viability of mineral resources has yet to be established (for example, MRZ-3, MRZ-4 or unstudied areas).

- Indirect incremental impacts could also occur where MRZ-2 lands are encroached upon by incompatible uses, particularly residences and other sensitive uses, and where development lies adjacent to MRZ-2 sites otherwise suitable for mining. The regulatory and mitigation measures outlined below would ensure such impacts are not cumulatively considerable.

- The incremental loss of areas with potentially viable mineral resources could also result in the need for development of mineral resources further away from the locations where they would be used. This would result in additional incremental contributions to other cumulative effects, such as traffic, air pollutants, noise and loss of biological habitat. See discussions under these sections, in particular Section 5.4 (Growth Inducement), for more information.

d. Mitigation

As described in detail in Section 4.14.3, a variety of measures would be implemented to avoid, reduce and minimize adverse cumulative impacts to mineral resources and resulting from mining activities. These include the following items:

Key Regulations and Programs: See Section 4.14.3 for details on each regulation.

- California Surface Mining and Reclamation Act of 1975 (SMARA), PRC sec. 2710 *et seq.*

- Ordinance No. 555 - Implementing SMARA in Riverside County

Key General Plan Policies: See Section 4.14.2 for the text of each policy.

- Open Space Element Policies: OS 14.1-14.5
- Land Use Element Policies: LU 9.6, 9.7 and 27.1-27.5

e. Significance

Implementation of all of the above regulations and General Plan policies would be sufficient to ensure that all of the incremental impacts listed above would be less than significant. As such, the project's incremental impacts to mineral resources and their availability would not be cumulatively substantial. Implementation of the above regulations and Riverside County General Plan policies would ensure that significant cumulative impacts to known mineral resources of regional or statewide significance are either avoided or minimized to less than significant.

14. Cumulative Effects on Noise

Section 4.15 (Noise) evaluates the potential for the project, GPA No. 960, to affect or be affected by noise and vibration levels within unincorporated Riverside County. This includes assessing the potential for exposure of Riverside County's population to new noise or vibration sources introduced as a result of the project, as well as the potential for increased or new populations near existing or new noise and vibration sources. It also analyzes the mitigation (both through regulatory compliance and EIR mitigation) necessary to ensure impacts are less than significant or mitigated to the extent feasible. Areas already covered in Section 4.15 are not repeated here; see that section directly for additional resource details.

Section 4.15 of this EIR provides a description of the existing noise environment within Riverside County, as well as modeling of existing and future noise impacts projected to occur as Riverside County builds out over time. This data includes Table 4.15-A (Definitions of Acoustical Terms), Table 4.15-B (Common Sound Levels and Their Noise Sources), Table 4.15-C (Human Responses to Groundborne Vibration), Table 4.15-D (Short-Term Ambient Noise Monitoring Results), Table 4.15-E (Long-Term Ambient Noise Locations), Table 4.15-F (Long-Term Ambient Noise Monitoring Results), Table 4.15-G (Traffic Noise Levels, Base Year Conditions [Existing, 2007]), Table 4.15-H (Incremental Noise Impact Criteria for Noise-Sensitive Uses), Table 4.15-I (Groundborne Vibration and Noise Impact Criteria), Table 4.15-J (County Ordinance No. 847 Sound Level Standards), Table 4.15-K (Land Use Compatibility for Community Noise Exposure), Table 4.15-L (Stationary Source Land Use Standards) (*aka* General Plan Table N-2), Table 4.15-M (Future Traffic Noise Levels, With and Without Project), Table 4.15-N (Typical Vibration Levels Associated with Construction Equipment), Table 4.15-O (Typical Maximum Noise Levels for Construction Equipment) and Table 4.15-P (Airport Compatibility Zones and Noise Levels).

It also includes Figure 4.15.1 (Short-Term and Long-Term Noise Monitoring Locations Map), Figures 4.15.2 – 4.15.4 (Typical Railroad Noise Contours, for various rail configurations), Figures 4.15.5 – 4.15.17 (Existing and Planned Noise Contours, for various public airports), Figure 4.15.18 (Military Airspace in Southern California), Figure 4.15.19 (Existing Noise Contours for Chocolate Mountain Aerial Gunnery Range), Figure 4.15.20 (March Joint Air Reserve Base, Noise Contours), Figure 4.15.21 (Military Training Airspace in the CMAGR Operating Area), Figure 4.15.22 (Special Use Airspace in Riverside County), Figures 4.15.23 – 4.15.39 (Future Noise Contours, for various public airports) and Figure 4.15.40 – 4.15.53 (Projected Roadway Noise Contours, for various street and highway configurations).

a. Existing Conditions

Land uses within Riverside County include a range of residential, commercial, institutional, industrial, recreational, agricultural and open space areas. In general, vehicular traffic is the dominant noise source in the unincorporated Riverside County area, with a myriad of other noises associated with daily life also contributing (engine startups, lawn mower operations, dogs barking, people conversing, music, construction activity, wind blowing, birds chirping, etc.) Significant noise also occurs from airplane traffic, railroads and various stationary sources as described below. Sensitive noise receptors typically include residences, schools, child-care centers hospitals, long-term health care facilities, convalescent centers and retirement homes.

Ambient Noise: Ambient noise measurements provide a snapshot of the existing noise environment for a given area and may be done in both short and long term locations (29 and 8 sites, respectively). As reported in Section 4.15, surveys of the existing noise environment were conducted in 2010 at locations representative of the areas of greatest anticipated growth across Riverside County in order to document the existing noise environment and capture the noise levels associated with typical daily operations and activities in unincorporated Riverside County. Short-term noise measurements locations are identified in Table 4.15-D and illustrated in Figure 4.15.1. Long-term noise measurement locations are identified in Table 4.15-E and also illustrated in Figure 4.15.1. The resultant monitoring data is summarized in Table 4.15-F. The full data set is included in the noise study (see Appendix EIR-7).

Roadway Noise: Freeway and highway traffic-related noise levels in unincorporated Riverside County were estimated from a variety of parameters, including traffic volumes, vehicle mix, vehicle speed and roadway geometry. In particular, average daily traffic (ADT) volumes are used for traffic noise modeling, as generated by the Riverside County Traffic Analysis Model (RIVTAM). Noise results for the cumulative scenarios were modeled by the same procedures using the cumulative traffic data set (based on the cumulative additional GPAs data set described in the introduction to Section 5.5). The resultant noise levels are modeled into traffic noise contours by computer to facilitate comparisons amongst roadways. Table 4.15-G provides the results of the base year (2007) traffic noise calculations adjacent to representative segments of the freeways and the major roads (traffic volumes above 6,000 ADT) in unincorporated Riverside County. Figures 4.15.40 to 4.15.53 in Section 4.15 show typical roadway noise contours.

Railroad Noise: Riverside County is traversed by three rail mainlines: BNSF Transcon, owned by Burlington Northern/Santa Fe (BNSF); UP Los Angeles Subdivision (UP LA Sub) and UP El Paso Line, both owned by Union Pacific (UP). On average, 85 freight trains per day pass through Riverside County and Metrolink operates 24 daily passenger (commuter rail) trains per day on the San Bernardino line and 38 per day on the West Riverside (Orange County) line. However, the amount of traffic along the principal railroad lines fluctuates considerably. Daily train traffic produces noise that may disrupt activities in proximity to railroad tracks, for example horns sounded at at-grade crossings. Figures 4.15.2, 4.15.3 and 4.15.4 in Section 4.15 provide typical railroad noise contours.

Air Travel Noise: Riverside County is served by seven public use general aviation airports along with a number of smaller airports and air fields. Most of the airports in Riverside County have published airport noise contour maps; see Figures 4.15.5 through 4.15.17 (existing and planned conditions) and Figures 4.15.23 through 4.15.39 (future conditions) in Section 4.15. Public use airports located in or affecting unincorporated Riverside County include: Banning Municipal, Bermuda Dunes, Blythe, Chiriaco Summit, Corona Municipal, Desert Center, Flabob, French Valley, Hemet-Ryan, Jacqueline Cochran Regional, Palm Springs International, Perris Valley, Riverside Municipal and (located in San Bernardino County) Chino. Noise contours from Los Angeles International and Ontario International airports are not included here because they do not extend to the Riverside County border.

Military Noise Sources: Riverside County is home to a number of military bases, including three active facilities: the Chocolate Mountain Aerial Gunnery Range (part of the Bob Stump Training Range Complex), March Joint Air Reserve Base and the Naval Surface Warfare Center. The Naval Warfare Center is not associated with aircraft, munitions or other significant military noise sources, however, the other two are active sources of these noises. See Figure 4.15.19 for noise contours for the Chocolate Mountain Aerial Gunnery Range and Figure 4.15.20 for noise contours for the March Joint Air Reserve Base. Military activities can have various effects on the ambient noise environment, mainly due to aircraft noise (including supersonic flight) and ordnance delivery. Ground-based noise and vibration can also be generated from artillery fire, ground-based arms, artillery and ordnance, detonation of high explosives and demolition charges, vehicles and operation of fixed and portable equipment, etc. Military facilities also have noise from typical non-military sources, such as vehicles and ORVs, commercial and industrial operations, landscaping and agricultural activities, etc.

Stationary Noise Sources: Stationary noise sources present in residential areas include HVAC and landscaping maintenance equipment (leaf-blowers, lawnmowers, etc.). Commercial uses often include larger, rooftop-mounted HVAC equipment which can produce point-source noise that most directly affects adjacent land uses. Amplified sound, e.g., from personal, home or automotive audio equipment, outdoor loudspeakers and music or theatrical performances, is another source. Conditional use permits, as well as Riverside County Ordinance No. 847, establish limitations on time and magnitude of noise for these sources.

Agricultural, Industrial, Recreational and Other Major Noise Sources: Agricultural operations may produce significant noise during planting and harvesting times from equipment operation. Agricultural noise may be disturbing to neighboring residential areas, particularly as urban development intrudes into agricultural lands. Industrial land uses can be associated with a variety of noise impacts, including shipping and loading facilities, concrete crushing facilities, recycling activities and other large mechanical or hydraulic equipment use, as well as natural gas extraction facilities, water treatment facilities and mining activities throughout Riverside County. Recreational lands and wildlife habitat are also impacted by noise from recreational uses, including sports park activities and ORV uses, particularly the uncontrolled use of ORVs. Noise intrusion into wildlife habitat drives off wildlife and, with prolonged use, may effectively reduce the amount of land used as habitat by various species.

b. Future Conditions

As noted above, for existing (baseline) conditions, noise data was developed both directly (through onsite measurement) and indirectly (through computer modeling), particularly for roadway noise levels. Similarly, for future conditions, computer modeling was used to estimate expected noise levels for a variety of situations, including various configurations and volumes for air traffic, railroad lines and roadways (both freeway and local networks). Future condition results for the expected build out conditions of Riverside County as it would exist if the General Plan was updated per GPA No. 960 (i.e., GPU/GP960 scenario) are presented in Section 4.15, as noted previously. Likewise, data for build out of the existing General Plan was developed as part of EIR No. 441, which was certified for the RCIP General Plan in October 2003, and is thus collected in Section 4.13 of that EIR. (Note: that data was not rerun as part of this analysis since the document has already been approved and the roadway network has since changed.) An additional set of data was run, however, for build out (future) conditions for the CULM GP scenario. Because the noise modeling results are voluminous, they are not included in this section. The data is presented instead in Appendix EIR-12.

Lastly, because mobile noise sources (i.e., vehicular traffic) generate the vast majority of sound affecting ambient noise levels, this cumulative analysis compares the roadway noise levels projected for each of the build out scenarios. Additional modeling for hypothetical air and rail noise levels were not performed as these transportation noise sources are minor contributors overall to the ambient noise environment. Also, future noise

contours for both air and rail are included in the figures presented in Section 4.15 of this EIR, for example, see Figures 4.15.23 through 4.15.39 for future noise conditions for airports within Riverside County.

Analysis of Riverside County noise data indicates that build out of any of the analyzed General Plan scenarios (including the General Plan as amended per GPA No. 960, i.e., the "GPU/GPA960 scenario") would increase noise levels as a result of increased development. These impacts would incrementally contribute to cumulatively considerable noise levels and result in significant noise exposures to sensitive receptors at both existing and future uses. As discussed in greater detail in Section 4.15, future development will contribute incrementally to cumulative noise impacts as Riverside County builds out (develops) over time pursuant to the Riverside County General Plan.

As demonstrated by both the existing setting and future noise level data, the noise conditions in which existing uses are occurring and, more importantly (for the purposes of this EIR), in which future uses and sensitive receptors would be exposed, have been increasing over time. Data indicate that the effect of General Plan build out, with or without the project's proposed General Plan changes, would be potentially significant for any development that introduces new sensitive receptors into areas in which exterior noise levels exceed 55 dBA. It would likewise be significant for incremental traffic noise increases attributable to the project that would result in either an existing noise level (at any point) that exceeded 55 dBA or in an incremental increase exceeding any of the levels noted in Table 4.15-H of Section 4.15.

c. Impacts

Future development will contribute incrementally to cumulative noise and vibration impacts, both short-term (construction) and long-term (operational) as Riverside County builds out over time pursuant to the Riverside County General Plan (regardless of scenario). Specific impacts of the severities indicated will include the following:

(1) Cumulatively Considerable Impacts

- Future development would incrementally increase rural, suburban and urban uses in Riverside County resulting in new noise-sensitive land uses in areas of existing excess noise or areas in which county growth would eventually lead to excess noise levels.

- Future development would contribute incrementally to increased traffic volumes on county roads, resulting in noise increases affecting sensitive land uses along existing and future roads. As a result, new development, particularly residential uses along and adjacent to major transit corridors, could be exposed to noise levels that exceed Riverside County's noise standards. Existing sensitive uses (residences, schools, etc.) would also be subject to these higher noise levels. Mitigation, such as setbacks and insulation are feasible for new uses. However, noise levels would increase incrementally over time to levels exceeding Riverside County noise standards, exposure of existing sensitive uses would be significant and unavoidable. Mitigation of the extremely small but numerous incremental increases that lead to this significant impact is infeasible due to the extremely widespread nature of the impacts.

- Future development would introduce new uses that increase noise levels several ways. First, new development would contribute noise from its construction and from the construction of needed new roads, infrastructure, public services, etc. Construction would result in temporary (short-term) noise impacts. Once completed, some of these new uses could be associated with stationary noise sources, possibly exceeding applicable noise standards. A stationary source that exposes sensitive receptors to

noise levels exceeding these standards may be significant if not reducible through regulatory compliance or mitigation measures.

- Under any of the General Plan build out scenarios, future development of noise-sensitive uses would occur in areas that either are currently exposed to or would be exposed to future traffic, airport or railroad noise levels that exceed the current standards, resulting in incremental increases in the number of people and properties exposed. Such development could also cause incremental exposure to noise from non-transportation (stationary) noise sources that exceed standards. Where setbacks and other mitigation measures are not feasible or do not sufficiently lower noise levels, such impacts would be cumulatively considerable.

- Future development associated with build out of any of the General Plan scenarios (including the with-project scenario) would contribute to incremental increases in traffic, resulting in corresponding incremental increases in traffic noise. Where this causes ambient noise levels to either exceed the threshold of acceptability (65 dBA CNEL, for example) or to become further unacceptable in areas already exceeding noise thresholds, such ambient noise increases would be cumulatively significant.

- For existing noise-sensitive land uses, however, due to the widespread and pervasive nature of noise impacts, it is generally not be feasible to mitigate the impact fully for all affected receptors. Thus, this cumulative impact would be significant and unavoidable, even with the implementation of all feasible mitigation.

- Future development near major rail lines or truck routes would also introduce new sensitive receptors into areas affected by existing groundborne vibration, incrementally increasing the people and properties exposed. In general, the potential for vibration-induced structural damage from such sources would be low, but disruptions or annoyance to occupants could occur if the uses were close enough to such sources. However, such vibration-induced disruption/annoyance can be avoided by not approving vibration-sensitive uses in areas where FTA vibration criteria (Table 4.15-I in Section 4.15, for example) are exceeded and requiring setbacks of sufficient distance to ensure vibration levels are within acceptable limits. Thus, compliance with regulations, as well as existing mitigation measures would ensure that operational vibration effects on new development are not cumulatively considerable.

(2) Non-Substantial Incremental Impacts

- Future development (of any of the General Plan build out scenarios, including the with-project scenario) will require construction activities that will cause incremental increases in temporary, short-term vibrations. These vibrations would be disruptive if located near sensitive receptors and will result in various levels of temporary groundborne vibration. Construction vibration can affect existing buildings (i.e., through structural damage) and their occupants (i.e., through activity disruption, annoyance, etc.) if they are located close enough to the construction sites. However, the temporary nature of the construction activities means that the disturbance would be of limited duration and, for this reason, would not be cumulatively significant. See also Impact 4.15-B discussion.

- Future development would necessitate construction activities which could affect nearby noise-sensitive receptors. Where these increases individually or cumulatively exceed applicable Riverside County standards, even if temporarily or only periodically, such impacts would be cumulatively considerable. In many cases, the peak sound levels would be extremely brief and overall ambient noise levels would remain within acceptable limits. At times, however, construction requirements and/or the proximity of the sensitive land use (e.g., within 150 feet or less) would make significant noise impacts unavoidable,

even though temporary. Because of the close distances involved, mitigation of sound levels to less than significant are technologically impossible. Thus, future development from any of the General Plan build out scenarios may result in cumulatively significant short-term noise impacts that would be significant and unavoidable.

- Future development resulting from build out of any of the General Plan scenarios may result in incremental increases in new noise-sensitive land uses that would be exposed to noise from operations at public and private airports, airstrips and helipads. Around larger public airports, noise levels can exceed acceptable standards in certain areas, as shown by noise-contour maps of existing, future and ultimate build out operational conditions for public airports. Compliance with ALUC, Riverside County and other applicable standards, as well as existing mitigation measures (see below), would ensure that airport-related noise impacts on future development are not cumulatively considerable.

d. Mitigation

As described in detail in Section 4.14.3, a variety of measures would be implemented to avoid, reduce and minimize adverse cumulative noise and vibration impacts. These include the following:

(1) Regulatory Compliance

Key Regulations and Programs: See Section 4.14.3 for details on each regulation.

- Federal Noise Control Act of 1972
- Federal Aviation Administration (FAA) Standards - CFR, Title 14, Part 150
- California Building Standards Code - CCR Title 24
- California Noise Insulation Standard - CCR Title 24
- Riverside County Airport Land Use Compatibility Plans
- County Ordinance No. 847 - Regulating Noise

Key General Plan Policies: See Section 4.14.2 for the text of each policy.

- Noise Element Policies: N 1.1, 1.2, 1.7, 2.2, 3.2, 3.5, 4.4, 6.4, 7.1-7.4, 9.3, 9.7, 10.1-10.4, 11.1-11.5, 12.1, 12.2, 13.1-13.4, 14.2, 15.2 and 16.1-16.3
- Land Use Element Policies: LU 1.8, 4.1, 15.1, 15.2, 16.9, 16.10, 29.6, 30.6, 31.3 and 32.10
- Open Space Element Policies: OS 14.5
- Circulation Element Policies: C 3.27-3.29, 6.7, 9.4, 9.5, 13.7, 14.3, 20.8 and 23.9

(2) CEQA Mitigation

The following CEQA mitigation measures (MMs) were adopted as part of certification of EIR No. 441 for the RCIP General Plan in October 2003 and remain applicable to GPA No. 960 and future General Plan implementing projects:

Existing Mitigation Measures: In EIR No. 441, a number of mitigation measures were imposed to reduce long-term impacts from mobile and stationary noise sources. These measures remain applicable to this project and would also apply to future development.

- **Existing MM 4.13.1A:** Prior to the issuance of any grading plans, the County [of Riverside] shall condition approval of subdivisions adjacent to any developed/occupied noise-sensitive land uses by requiring applicants to submit a construction-related noise mitigation plan to the County [of Riverside] for review and approval. The plan should depict the location of construction equipment and how the noise from this equipment will be mitigated during construction of the project through use of such methods as:

  a. The construction contractor shall use temporary noise attenuation fences where feasible, to reduce construction noise impacts on adjacent noise sensitive land uses.

  b. During all project site excavation and grading on site, the construction contractors shall equip all construction equipment, fixed or mobile, with properly operating and maintained mufflers, consistent with manufacturers' standards. The construction contractor shall place all stationary construction equipment so that emitted noise is directed away from sensitive receptors nearest the project site.

  c. The construction contractor shall locate equipment staging in areas that will create the greatest distance between construction-related noise sources and noise sensitive receptors nearest the project site during all project construction.

  d. The construction contractor shall limit all construction-related activities that would result in high noise levels to between the hours of 7:00 am and 7:00 pm Monday through Saturday. No construction shall be allowed on Sundays and public holidays.

- **Existing MM 4.13.1B:** The construction-related noise mitigation plan required shall also specify that haul truck deliveries be subject to the same hours specified for construction equipment. Additionally, the plan shall denote any construction traffic haul routes where heavy trucks would exceed 100 daily trips (counting those both to and from the construction site). To the extent feasible, the plan shall denote haul routes that do not pass sensitive land uses or residential dwellings. Lastly, the construction-related noise mitigation plan shall incorporate any other restrictions imposed by [Riverside] County staff.

- **Existing MM 4.13.2A:** All new residential developments within the County [of Riverside] shall conform to a noise exposure standard of 65 dBA L_{dn} for outdoor noise in noise-sensitive outdoor activity areas and 45 dBA L_{dn} for indoor noise in bedrooms and living/family rooms. New development, which does not and cannot be made to conform to this standard, shall not be permitted.

- **Existing MM 4.13.2B:** Acoustical studies, describing how the exterior and interior noise standards will be met, shall be required for all new residential developments with a noise exposure greater than 65 dBA L_{dn}. The studies shall also satisfy the requirements set forth in Title 24, Part 2 of the California [Building]

Code (Noise Insulation Standards), for multiple-family attached homes, hotels, motels, etc. No development permits or approval of land use applications shall be issued until an acoustic analysis is received and approved by the [Riverside] County Planning Department.

- **Existing MM 4.13.2C:** The County [of Riverside] shall require that proposed new commercial and industrial developments prepare acoustical studies, analyzing potential noise impacts on adjacent properties, when these developments abut noise-sensitive land uses. The County [of Riverside] will require that all direct impacts to noise-sensitive land uses be mitigated to the maximum extent practicable.

- **Existing MM 4.13.2D:** Ensure that all new schools, particularly in subdivisions and specific plans, are sited more than 2 miles away from any airport.

- **Existing MM 4.13.3A:** Acoustical studies shall be required for all new noise-sensitive projects that may be affected by existing noise from stationary sources.

- **Existing MM 4.13.3B:** To permit new development of residential and noise-sensitive land uses where existing stationary noise sources exceed [Riverside] County's noise standards, effective mitigation measures shall be implemented to reduce noise exposure to or below the allowable levels of the zoning code/noise control ordinance.

- **Existing MM 4.13.3C:** No industrial facilities shall be constructed within 500 feet of any commercial land uses or within 2,800 feet of any residential uses without the preparation of a noise impact analysis. This analysis shall document the nature of the industrial facility as well as "noise producing" operations associated with that facility. Furthermore, the analysis shall document the placement of any existing or proposed commercial or residential land uses situated within the noted distances. The analysis shall determine the potential noise levels that could be received at these commercial and/or residential land uses and specify measures to be employed by the industrial facility to ensure that these levels do not exceed [Riverside] County noise requirements. Such measures could include, but are not limited to, the use of enclosures for noisy pieces of equipment, the use of noise walls and/or berms for exterior equipment and/or on-site truck operations, and/or restrictions on hours of operations. No development permits or approval of land use applications shall be issued until an acoustic analysis is received and approved by [Riverside] County staff.

- **New Mitigation Measures:** The new mitigation measure below is proposed to help minimize the effect of operational vibrations on existing uses. Compliance with this measure would ensure that potential adverse impacts of operational groundborne vibrations on new development are reduced to less than significant levels.

- **New MM 4.15.B-N1:** Prior to the issuance of any grading permit for new development involving vibration-sensitive land uses (which shall include, but not be limited to: hospitals, residential areas, concert halls, libraries, sensitive research operations, schools and offices), the project proponent shall provide evidence to the County of Riverside that placement of such uses within the area would not exceed groundborne vibration or groundborne noise impact criteria identified by the FTA (for example, the standards shown in Table 4.15-I [of Section 4.15] of this EIR) or as otherwise deemed appropriate for the situation by the County of Riverside.

e. Significance

As outlined above, future development accommodated by any of the General Plan build out scenarios, including that with the project (GPA No. 960), would result in cumulatively considerable increases in ambient noise levels and in the number of people and noise-sensitive land uses exposed to substantial noise levels. It would also incrementally increase ambient noise levels throughout Riverside County to cumulatively considerable levels in some places (where regulatory and mitigation measures are insufficient to reduce noise impacts). These measures would be sufficient when applied to new development, but are not feasible for existing development. Thus, for impacts to existing noise-sensitive uses, however, the wide-spread, diffuse nature of the noise impacts, particularly those from increase traffic volumes resulting from build out of any of the General Plan scenarios, as well as from the project itself, would result in cumulatively significant impacts that cannot be feasibly reduced to acceptable noise levels. Thus, the project would result in incremental generation or cumulative exposure of existing uses to excessive noise in some areas, or would result in a cumulatively substantial permanent or temporary increase in ambient noise levels. These cumulative impacts would be significant and unavoidable for the reasons outlined herein. For the impacts listed as not considerable, implementation of the regulatory programs and mitigation measures listed above would be sufficient to ensure that incremental impacts are not cumulatively significant. This includes incremental airport noise impacts and groundborne vibration impacts.

15. Cumulative Effects on Parks and Recreation

Section 4.16 (Parks and Recreation) of this EIR discusses existing parks and recreational facilities, including trails and bikeways, within Riverside County, as well as the sources used and the updates made to them for this data. It also analyzes the demand on existing and the need for future parks, trails and recreation facilities that would arise from future development accommodated by the changes proposed by the project, GPA No. 960, as well as the mitigation (through regulatory compliance) necessary to ensure impacts are less than significant. As a result, areas already covered in Section 4.17 are not repeated here; see section directly for additional resource details.

Section 4.16 of this EIR provides a complete description of existing park, trail and recreation facilities within Riverside County, as well as analysis of the existing and future need for such facilities projected as Riverside County builds out. This data includes Table 4.16-A (Park and Recreation Jurisdictional Totals), Table 4.16-B (Existing and Proposed Parks and Recreation) and Table 4.16-C (Theoretical Parkland Needs, With and Without the Project). It also includes Figure 4.16.1 (Existing Parks and Recreational Resources), Figure 4.16.2 (Countywide Trails and Bikeways Map), Figure 4.16.3 (Existing Trail Cross-Sections) and Figure 4.16.4 (Proposed Trail Cross-Sections).

a. Existing Conditions

Riverside County parks, trails, bikeways and other recreational areas and uses offer residents and visitors a myriad of recreational opportunities, while providing valuable buffers within built-up urban spaces. The locations of existing parks and recreation areas in unincorporated Riverside County are shown in Figure 4.16.1. A summary of all the existing parks within unincorporated Riverside County is provided in Table 4.16.B. Large swaths of open space and recreational lands fall under state or federal jurisdictions and many of these facilities, particularly the National Parks and Forests stretch beyond Riverside County. Table 4.16-A summarizes the parks and recreation areas under state and federal jurisdiction.

The County of Riverside currently maintains 35 regional parks encompassing roughly 22,300 acres total. More than half of these parks are located in the western portion of Riverside County, with the other facilities scattered throughout the eastern desert, central mountains and Colorado River regions. There are four park and recreation

districts covering portions of Riverside County: Beaumont-Cherry Valley, Desert, Jurupa and Valleywide. Together, they provide approximately 27 neighborhood and community parks on approximately 275 acres of parkland. Additionally, some County Service Areas (for example, CSA 134) also provide local park or trail maintenance services, often for parks and trails constructed as part of new development projects. The cities within Riverside County also offer numerous park and recreational facilities; currently 215 parks spanning over 1,500 acres. However, these city facilities are outside the scope of the County of Riverside's jurisdiction (though they may still be affected by growth within Riverside County, see discussions below). Note: the cities of Jurupa Valley and Eastvale are treated as unincorporated land for the purposes of this EIR section since their incorporation dates (July 2011 and October 2010) post-date this EIR's NOP date of April 2009.

The Riverside County Regional Park and Open Space District (Park District) acquires, manages, develops and maintains 27 neighborhood and regional parks throughout Riverside County. The Park District maintains approximately 71,700 acres of land including 150 miles of multi-purpose recreational trails, seven archeological sites, 16 wildlife reserves and natural areas. It also operates one boxing facility, manages four nature centers and patrols six historic sites, and provides annual interpretive programs to more than 82,000 students. The Park District's park and open space resources provide enjoyment to residents of Riverside County and visitors alike. There are also a number of off-road vehicle (ORV) parks within Riverside County operated by the USFS and BLM on federal lands, as well as numerous private recreational facilities throughout the county.

There are also many miles of trails located throughout Riverside County in a variety of designs for pedestrians, equestrians, bicyclists and (on some) all-terrain vehicle enthusiasts to enjoy. The General Plan outlines standards for several trail types. Existing trails and proposed trail alignments are shown in Figure C-7 of the General Plan for the countywide system; more detailed maps are included in the Area Plans. Figure 4.16.2, below, shows the countywide system map. In addition to pedestrian uses, the Riverside County trail system includes plans for bicycle use, with three types of bike paths plus a combination trail for bikes and pedestrians. The General Plan Circulation Element contains specifications and cross-sections for each of these trails, as well as standards for their construction and maintenance. See Figure 4.16.3 for existing trail cross-sections and Figure 4.16.4 (later in this section) for proposed cross-sections.

As part of GPA No. 960, an extensive revamping of the standards and specifications for both trails and bikeways is proposed to enable the realization of trails types that better suit the level of use and connectivity needed. This includes revising the existing "regional trail" standard to include two trail sub types that distinguish between the urban and rural usage associated with developed areas and the open space trails used more for regional connectivity and in open space both within and between developed areas. Other lesser changes are also proposed for other trails and bikeways. For text of relevant General Plan policies and trail standards, including those revised as part of GPA No. 960, see Section 4.16.3.

b. Future Conditions

In general, the introduction of new development into an area brings with it an attendant new demand for resources, including recreational opportunities and, in particular, parklands. State laws, in particular the Quimby Act, establish minimum standards for the amount of parkland to be provided for a given population. Per its implementation via Riverside County Ordinance No. 460, this minimum is 3.0 acres of parkland per 1,000 population or comparable in-lieu fee payment. Individual park and recreation districts or CSAs may have other standards.

Spatial analysis was performed to examine the cumulative effects of the various General Plan build out scenarios on demand/need for recreational opportunities. In addition, theoretical modeling was performed for each build out scenario to examine the hypothetical park needs associated with each as dictated by Quimby Act standards.

These analyses reflect the range of impacts associated with *theoretical* parkland needs for the specific land uses indicated for each scenario. See Section 4.16.5.B for details on the specifications, assumptions and methodology applied to the analyses presented here.

Table 5.5-W (Cumulative Theoretical Parkland Effects), below, shows the cumulative conditions for the three General Plan build out scenarios examined in this section: Existing General Plan (CURR GP), the Updated General Plan as per GPA No. 960 (GP/GPA960) and the cumulative General Plan as per the additional proposed GPAs through 2009 (CULM GP). The same modeling procedures were used to estimate theoretical park acreage needs based on the populations predicted (i.e., under Section 5.5.2, cumulative population and housing effects) for each build out scenario. By controlling these variables in the modeling process, valid comparisons amongst the scenarios are possible.

Note, these data should not be construed as the *actual* specific park demands that would arise for a given area. Such determinations will be made on a project-by-project basis as development occurs and may vary based on the surrounding area. For areas within a park and recreation district, that agency will have final say on the future park and recreational facilities needed, as well as where, how and to what standards such facilities are developed. Each agency has developed its own plans, standards and requirements. Thus, because of the scope of these various countywide build out scenarios, individual districts and area plan calculations were not feasible for this analysis.

Per Table 5.5-W, General Plan build out will contribute incrementally to growth in populations throughout Riverside County which will utilize existing recreational facilities and add to the demand for additional recreational uses. Even with no project, build out of the current General Plan (CURR GP scenario) shows that over *3,400* ~~1,500~~ acres of additional parklands, more than double the existing amount, will be necessary to serve expected urban/suburban populations. The project (GPU/GPA960 scenario) would incrementally increase the need for parklands by *2%* ~~3%~~ (*80* ~~140~~ acres) and the cumulative (CULM) build out scenario would *also* incrementally add *50* ~~280~~ acres ~~(7%)~~. Neither of these increases is cumulatively considerable in terms of demand for additional parklands.

Table 5.5-W: Cumulative Theoretical Parkland Effects

PARKLANDS *(Total Acres)*[1]	Existing[2] Conditions	%	General Plan Build Out Scenarios					
			CURR GP[3]	%	GPU/ GPA960[3]	%	CULM GP[3]	%
Residential, Urban/Suburban	*1,540*	*92%*	*3,430*	*68%*	*3,460*	*69%*	*3,560*	*69%*
Residential, Rural/Agriculture	*40*	*2%*	*740*	*15%*	*700*	*14%*	*720*	*14%*
Residential, Interface/Wildand	*90*	*5%*	*910*	*18%*	*840*	*17%*	*850*	*17%*
Total	***1,670***		***5,080***		***5,000***		***5,130***	
Difference (from EXIST)	---	---	*+ 3,410*	*204%*	*+3,330*	*+199%*	*+3,460*	*+207%*
Difference (from CURR)	---	---	---	---	*+50*	*+1%*	*+50*	*+1%*

Footnotes:
1. Calculations use 3.0 acres of parkland per 1,000 population. All values rounded to nearest 10.
2. "Existing" values per theoretical baseline calculations, see applicable portion of Section 4.16 for actual values.
3. Build out scenarios: CURR GP = Current (*2009* ~~2008~~) General Plan; GP/GPA960 = Current (*2009* ~~2008~~) General Plan with changes proposed by GPA No. 960; TOT CULM GP = Current (*2009* ~~2008~~) General Plan, plus GPA No. 960, as well as changes proposed by existing GPAs approved or applied for through the end of 2009 (see Table 5.5-A).
4. Commercial uses include CR, CO and CT. Industrial uses include HI, LI and BP. Uses too variable for factors omitted.
5. *See Tables 20.5.a and 20.5.b in Appendix EIR-11 for more detailed data used.*

Source: Riverside County Planning Dept., Project Application Data, 2013 *and 2014*. Factor from EIR No. 441, 2003.

Growth pressures within Riverside County will result in development that causes the incremental increases in use of existing parks, trails and other recreational facilities, both within unincorporated Riverside County and its cities, regardless of the General Plan build out scenario. Provision of additional facilities, as per the policies and regulations discussed below, would offset many of these impacts. However, due to the sheer size of the population growth, overall impacts to existing facilities would be cumulatively considerable for any of the build

out scenarios, including that encompassing GPA No. 960. Similarly, future development pursuant to any of the scenarios would also increase demand for additional trails and bikeways within new development and increase use of existing trails and bikeways, particularly those that connect new uses to existing destinations (schools, bus stops, retail areas, etc.).

c. Impacts

Future development will contribute incrementally to cumulative impacts to parks, trails and other recreational facilities as Riverside County builds out over time pursuant to the Riverside County General Plan (regardless of scenario). Specific impacts of the severities indicated will include the following:

(1) Cumulatively Considerable Impacts

- Future development per any of the scenarios would result in population growth in Riverside County, incrementally increasing the number of people using existing neighborhood and regional parks, trails, bikeways and other recreational facilities. Where new facilities are not provided to offset such increased use, this would contribute to cumulatively substantial increases in the wear and tear on existing facilities.

(2) Non-Substantial Incremental Impacts

- As noted earlier, future development per any of the scenarios would result in population growth in Riverside County, incrementally increasing the number of people using existing neighborhood and regional parks, trails, bikeways and other recreational facilities. As compared to the existing (CURR) General Plan build out scenario, incremental effects on parks and recreational facilities, including trails and bikeways, associated with either the with-project (GPU/GPA960) scenario or the cumulative (CULM) scenario would be less than significant (3%-7%).

- Incremental population growth over time will necessitate construction of new or expansion of existing parks and recreational facilities. The construction or expansion of such facilities could have an adverse physical effect on the environment. However, compliance with existing regulations, Riverside County ordinances, mitigation measures from EIR No. 441 and General Plan policies, as outlined throughout this EIR, would be sufficient to ensure that resultant environmental impacts are less than significant.

d. Mitigation

As described in detail in Section 4.16.3, a variety of regulatory compliance measures would be implemented to avoid, reduce and minimize adverse cumulative park, trail and recreation impacts. These include the following:

Key Regulations and Programs: See Section 4.16.3 for details on each regulation.

- Quimby Act - CGC section 66477

- Ordinance No. 328 - Rules and Regulations for the Government of County or District Owned or Operated Parks and Open Space Areas

- Ordinance No. 460 - Regulating the Division of Land

Key General Plan Policies: See Section 4.16.3 for the text of each policy.

- Land Use Element Policies: LU 9.2 and 25.1-25.4
- Open Space Element Policies: OS 20.3, 20.5 and 20.6,
- Circulation Element Policies: C 4.9, 15.1-15.4, 16.1, 16.2, 16.7, 17.2, 17.3 and 18.1-18.3

e. Significance

Implementation of all of the above regulations and General Plan policies would be sufficient to ensure that all of the non-substantial incremental cumulative impacts listed above would be less than significant. As such, the project's incremental increase in demand for additional opportunities and the environmental effects of meeting such needs, would not be cumulatively considerable for build out of the General Plan as amended either per the proposed project (GPA No. 960) or the cumulative projects list (see Table 5.5-A). However, in terms of wear and tear on existing park and recreation facilities, including trails, incremental increases in use as county population grows will be cumulatively significant for either cumulative scenario (with-project or with all GPAs).

16. Cumulative Effects on Public Facilities

Section 4.17 (Public Facilities) of this EIR discusses existing public facilities, such as fire and law enforcement and solid waste disposal (landfills), as well as medical, educational and library facilities. Infrastructure not covered in Section 4.17 are discussed elsewhere; e.g., parks and recreation in Section 4.16, electricity and other energy sources in Section 4.10 and water supplies in Section 4.19. Section 4.17 discusses the data sources used for this topic and any General Plan updates made to them. It also analyzes the demand on existing public facilities and the need for future facilities that would arise from future development accommodated by the changes proposed by the project, GPA No. 960, as well as the mitigation (both through regulatory compliance and EIR mitigation) necessary to ensure individual project impacts are less than significant. As a result, areas already covered in Section 4.17 are not repeated here; see that section directly for additional resource details.

Section 4.17 of this EIR provides a complete description of existing public facilities within Riverside County, as well as analysis of the existing and future need for such facilities projected as Riverside County builds out. Specifically, fire protection is covered in Section 4.17.2 and includes: Figure 4.17.1 (Fire Stations in Riverside County) and Figure 4.17.2 (Fire Responsibility Areas), plus Table 4.17-A (Cities Served by The Riverside County Fire Department, i.e., CalFire), Table 4.17-B (CalFire Aid Agreements), Table 4.17-C (Fire Stations Serving Riverside County), Table 4.17-D (Theoretical Fire Station Needs With and Without the Project), Table 4.17-E (Theoretical Fire Station Needs for Areas of New Development Potential) and Table 4.17-F (Comparison of Theoretical Fire Support Needs at General Plan Build out).

Law enforcement is covered in Section 4.17.3 and includes: Figure 4.17.3 (Police and Sheriff Station Locations), plus Table 4.17-G (County Sheriff's Department Substations Serving Riverside County), Table 4.17-H (Theoretical Law Enforcement Needs With and Without the Project), Table 4.17-I (Theoretical Law Enforcement Needs for New Development Potential Area) and Table 4.17-J (Theoretical Law Enforcement Needs at General Plan Build out).

Solid waste management is covered in Section 4.17.4 and includes: Figure 4.17.4 (Landfill Locations in Riverside County), plus Table 4.17-K (Solid Waste Disposal Facilities in Riverside County), Table 4.17-L (Active Landfills in Riverside County), Table 4.17-M (Fifteen-Year Disposal Capacity Projections for Riverside County), Table 4.17-N (Theoretical Solid Waste Generation for Existing and Build out Conditions), Table 4.17-O (Theoretical

Solid Waste Generation for New Development Potential Areas) and Table 4.17-P (Comparison of Theoretical Solid Waste Generation at General Plan Build out).

Schools are covered in Section 4.17.5, which includes: Figure 4.17.5 (Public School Locations in Riverside County), plus Table 4.17-Q (Total School Enrollment for Riverside County School Districts), Table 4.17-R (Theoretical Student Generation With and Without the Project), Table 4.17-S (Theoretical Student Generation for New Development Potential Areas), Table 4.17-T (Theoretical Student Generation at General Plan Build out) and Table 4.17-U (Total Project-Related Student Population Changes by School District).

Libraries are covered in Section 4.17.6, which includes: Figure 4.17.6 (County Public Library Locations in Riverside County), plus Table 4.17-V (County Libraries Serving Riverside County) and Table 4.17-W (Theoretical Library Services Need Projections).

Medical facilities are covered in Section 4.17.7, which includes: Figure 4.17.7 (Hospital Locations in Riverside County), plus Table 4.17-X (Riverside County Family Care Clinics and Related Facilities), Table 4.17-Y (Theoretical Medical Service Needs With and Without the Project), Table 4.17-Z (Theoretical Medical Needs for Areas of New Development Potential) and Table 4.17-AA (Theoretical Medical Service Needs at General Plan Build out).

a. Existing Conditions

Fire Protection Services: The County of Riverside contracts with the State of California (the California Department of Forestry and Fire Protection, also now known as "CalFire") for fire protection. Under CalFire "Riverside Operational Unit" management, the Riverside County Fire Department (RCOFD) operates 95 fire stations in 17 battalions with about 230 pieces of equipment. Fifty-one of these stations, as well as three stations operated directly by CalFire, are located in the unincorporated portion of Riverside County. See Table 4.17-A. In addition to all of unincorporated Riverside County, the CalFire Riverside Unit serves small portions of San Diego and Orange counties, and also operates 18 city fire departments and one community services district (CSD) fire department for the Rubidoux CSD. The RCOFD also responds to a number of cities and communities through mutual and automatic aid agreements and also provides dispatch under contract. See Table 4.17-B.

Within its service area, RCOFD provides fire suppression, emergency medical, rescue and fire prevention services and is equipped to fight both urban and wildland emergency conditions. The department also provides weed abatement, ambulance response, swift water rescue and a Level 1 hazardous material team. The State of California (CalFire) also has primary responsible responsibility for managing fires on lands designated "State Responsibility Areas" (SRAs). A variety of local fire agencies, for example city fire departments, have jurisdiction over "Local Responsibility Areas" (LRAs). And on federal lands, Federal Responsibility Areas (FRAs), federal agencies (BLM or U.S. Forest Service) are responsible. Within Riverside County, the CalFire Riverside Unit is responsible for 544,180 acres of SRA, plus 2,630 acres in San Diego County and 620 acres in Orange County. As the contract fire protection agency for various cities within Riverside County, CalFire is also responsible for 13,206 acres of LRA land within Riverside County. Other agencies, such as city fire departments, etc., are responsible for 572 acres of LRA. On federal lands (FRA) within Riverside County, the BLM is responsible for 52,650 acres and the U.S. Forest Service for 62,520 acres. For a full discussion on SRAs, LRAs, etc., see Section 4.13 (Hazardous Materials and Safety).

Law Enforcement Services: Riverside County provides community policing and operates and maintains a number of correctional facilities under the Riverside County Sheriff's Department, which has 4,500 established positions, including roughly 2,300 sworn personnel. The Sheriff's Department is a "demand response" agency that maintains limited patrol services. Nine Sheriff Department stations are located throughout Riverside County

to provide area-level community service. See Table 4.17.3-A in Section 4.17.3.A for the locations of these substations. The Sheriff's Department also operates the Moreno Valley Police Department station in the City of Moreno Valley, providing law enforcement services under contract. The Sheriff's Department also operates five adult correction or detention centers located throughout Riverside County. The Riverside County Probation Department operates the juvenile detention facilities.

The County of Riverside requires the payment of developer mitigation fees prior to the final inspection by the Building and Safety Department for residential units. The fees are for the construction and acquisition of public facilities. The Sheriff's Department's ability to support the needs of future growth is dependent upon their financial ability to hire additional deputies. In addition, a growing population would require that the Sheriff's Department secure sites and construct new detention facilities on a timely basis.

Solid Waste Management: The Riverside County Waste Management Department (RCWMD) is responsible for the efficient and effective landfill disposal of non-hazardous county waste. To accomplish this, the RCWMD operates six active landfills and administers a contract agreement for waste disposal at the private El Sobrante Landfill, as well as oversees several transfer station leases and a number of recycling and other special waste diversion programs. As all of the private haulers serving unincorporated Riverside County ultimately dispose of their waste to County-owned or contracted facilities, they are not further discussed separately here; their county waste is included in the data discussed here.

All of the active landfills currently located in Riverside County are rated as Class III landfills per CCR Title 27 and only accept nonhazardous, municipal solid wastes. Franchise solid waste collection companies are granted permits to collect commercial and residential waste throughout unincorporated Riverside County under the County of Riverside's general operating authority. These companies are regulated by the Riverside County Department of Environmental Health (RCDEH). In addition, Riverside County landfills accept wastes collected in incorporated cities. Within these cities, solid wastes are either collected by the city as a municipal service or are collected by private firms pursuant to a franchise agreement with the city.

The RCWMD is specifically charged with the responsibility of: 1) implementing programs that adhere to the goals, policies and objectives outlined in Riverside County's Source Reduction and Recycling Element (SRRE) to ensure that unincorporated Riverside County achieves 50% diversion of solid waste from landfill disposal; 2) implementing programs that adhere to the goals, policies and objectives outlined in Riverside County's Household Hazardous Waste Element to reduce the amount of HHW disposed within landfills; 3) continuing to meet the solid waste disposal needs of all Riverside County residents into the future; and 4) maintaining and updating the CIWMP and reporting to the CIWMB on Riverside County's progress in complying with AB 939.

As part of its long-range planning and management activities, the RCWMD also ensures that Riverside County has a minimum of 15 years of capacity, at any time, for future landfill disposal. The RCWMD also maintains closed landfills and historic "dump sites" within the county and is involved in the closure and post-closure of 30 disposal sites, requiring in some cases construction, monitoring and maintenance activities. In general, waste originating from anywhere within Riverside County may be accepted for disposal at any of Riverside County's sites. In practice, to minimize truck traffic and vehicular emissions, each landfill has a service area that dictates where trash is received from. In Section 4.17.4.A, Tables 4.17-K and 4.17-L describe the solid waste disposal facilities in Riverside County.

All RCWMD sites have the potential for expansion. Currently, the Lamb Canyon Landfill is in the design and permitting stage for its next expansion (Phase 3) to provide capacity for an additional 30-plus years beyond the estimated closure date of 2021. The closure dates listed for RCWMD sites are estimated dates and subject to change based on actual tonnage received and any future RCWMD re-permitting activities. The specific

operational details, such as daily, yearly and lifetime capacities, intake volumes and estimated closure dates, are provided in Table 4.17-K for each active landfill serving Riverside County. The 15-year projection of disposal capacity is prepared each year by the RCWMD as part of the annual reporting requirements for the Countywide Integrated Waste Management Plan (CIWMP). The most recent 15-year projection submitted to the State Integrated Waste Management Board by the RCWMD is shown in Table 4.17-L. Riverside County's projection is disposal-based, accounting for both growth in disposal needs or demand (4% per year) and diversion requirements.

Schools: A total of 23 school districts serve Riverside County. Most of these are "Unified School Districts" providing schooling for grades K (kindergarten) through 12. Occasionally, differing grades are provided by separate districts, e.g., the Perris Union High School District only serves grades 9-12. Riverside County Office of Education (RCOE) provides educational and administrative support services to the school districts and over 430,000 students living in Riverside County. It also acts as an intermediary between the State of California and the local school districts.

RCOE reports a total of 467 K-12 school sites, including 17 charter schools, 273 elementary sites, 75 middle/junior high sites, 69 high school sites and 33 continuation/adult education sites, as well as 16 Head Start/preschool program sites. RCOE also reports that the average State of California funding per pupil is $5,011 for elementary districts, $6,022 for high school districts and $5,239 for unified districts. The Riverside County Public School Directory for 2010-2011 indicates there are more than 18,740 teachers and 17,480 non-teaching school employees serving the County of Riverside. Table 4.17-P in Section 4.17.5.A indicates student enrollment levels for the 2009-2010 and 2010-2011 school years. The 18 charter schools and four "independent study" schools located in Riverside County are privately run and not included. Since provision of private educational services, such as charter schools, is based on economic factors, rather than state mandate, they are not further discussed or analyzed in this section. There are also several community college districts providing advanced educational instruction in Riverside County, as well as a number of private, public and technical/professional schools of higher education.

Overcrowding in public schools is caused by increases in student enrollment. In April 2003 (the most recent year of data available), the State Department of Education established a list of schools and school districts identified as overcrowded under criteria set by the State of California. To be classified as a "Critically Overcrowded School," a school must have a pupil density greater than 115 pupils per acre for grades K-6 and 90 pupils per acre for grades 7-12. Within Riverside County, five elementary schools within the Riverside Unified School District were identified as such. No other schools or school districts within Riverside County were included in the state list.

Libraries: The County of Riverside operates a system of 32 libraries and two book mobiles. The names and locations of these county libraries are presented in Table 4.17-V in section 4.17.6.A. The Riverside County Library System operates an automated network that currently deploys over 350 computer/terminal workstations in a number of library branches and can also be accessed by Riverside County residents via Internet. The library system manages the library catalog of the 1.3 million items in the library system and the annual checkout of over 3.5 million books, audios and videos. In 2010, the Riverside County Library System reported over 681,000 "registered borrowers" utilizing county library services. In addition to providing the opportunity to review and/or check-out materials for personal use, the County of Riverside also operates a number of specific programs including adult and family literacy, and after-school and pre-school programs. Based on 2010 reported registered borrowers (681,117) and current square footage of library facilities available (333,884), at present facilities provide approximately 0.49 square feet of space per registered borrower (not the county population as a whole).

The County of Riverside's ability to support the needs of future growth is dependent upon its ability to secure sites for, construct and stock new libraries on a timely basis. At present, there is no specific funding mechanism for expansion of library facilities.

Medical Facilities: The County of Riverside operates the Riverside County Regional Medical Center (RCRMC) in Moreno Valley, which in turn operates a number of adjunct clinics. The Riverside County Department of Public Health also operates ten separate clinics throughout the county. Additional medical facilities and services, such as private/for profit and municipal facilities, exist within the county and are not addressed in this analysis. The RCRMC is a 520,000-square foot state-of-the-art tertiary care and level II adult and pediatric facility, licensed for a total of 439 beds and with a staff of approximately 2,100. The RCRMC provides upwards of 200,000 annual patient visits in its specialty outpatient clinics and 100,000 annual patient visits to its emergency room/trauma unit. The community-based clinics operated by the Riverside County Department of Public Health provide a wide array of family care services. See Table 4.17.6-A for full list of clinics and locations.

b. Future Conditions

The ongoing growth of Riverside County over time will introduce people, property and structures into previously undeveloped areas and also increase urban densities through infill and expansion, all of which would require adequate public services and facilities to ensure their health, safety and well-being. In terms of future conditions, a variety of data and analyses were collected or performed to determine what effects build out of Riverside County over time (in any of the respective scenarios, including cumulative) would have on existing public facilities, as well as the demand for future services. The results of these analyses are shown in tables below. For the methods used in calculating the individual metrics shown, see the respective subsections of Section 4.17.

The tables show the cumulative conditions for the three General Plan build out scenarios examined in this section: Existing General Plan (CURR GP), the Updated General Plan as per GPA No. 960 (GP/GPA960) and the cumulative General Plan as per the additional GPAs proposed or approved through 2009 (CULM GP) (see Table 5.5-A). See Sections 5.5.1 and 5.5.2 for specifics on each scenario.

It should be noted that the public services addressed here encompass the jurisdictions and responsibilities of numerous independent public agencies, both within and at times outside of Riverside County. Thus, for baseline (existing) services a theoretical value is used rather than actual data because of the variability in existing conditions and the amount of data available. See table footnotes for specifics. For all of the metrics, the same modeling procedures used to estimate theoretical needs in Section 4.17 were used. Estimates consist of *theoretical* data because specific area-by-area calculations for each resource, using each independent agency's own variables and procedures were beyond the scope of this programmatic analysis. Also, controlling these variables in the modeling process by using standardized factors countywide enables valid comparisons amongst the various scenarios without inconsistencies caused by varying models amongst agencies.

These data should not be construed as the *actual* specific demands for public facilities that shall arise for a given location. Such determinations will be made on a project-by-project basis as development occurs and may vary based on the surrounding area. For resources or areas overseen by a specific public entity (e.g., individual school districts), that agency will have final say on the future facilities needed, as well as where, how, when and to what standards such facilities are ultimately developed. Further, each agency has its own plans, standards and requirements that will apply. The values presented here are for comparative planning purposes only.

The theoretical projections are also based on the assumption that all the land uses proposed under each scenario are actually developed fully and as mapped/planned. As such, each represents the theoretical, worst-case scenario and likely over-states the actual real-world development potential likely to result. Actual future development of

individual parcels and areas mapped in the various build out scenarios, including those of GPA No. 960, are subject to the discretion of many hundreds to thousands of individual property owners, including private individuals, business entities and even various public agencies and other entities. The County of Riverside has little to no control over the decision to propose development (new or redeveloped) on a given site although the County of Riverside is the entity with discretion for review and approval of such development applications for most cases within unincorporated Riverside County. Demand for additional development is often a result of many interrelated factors, including population growth and economic demand, as well as location, local supply, infrastructure availability, costs, etc.

Review of the theoretical demand calculations in the tables *below* ~~above~~ reveal several trends, which is expected since each is derived from the same population and land use data. In general, build out of the current General Plan (CURR scenario) will result in cumulatively significant impacts across the gamut of public services. For many, the demand for services will be roughly doubled over the next 50 or so years. This applies to schools, as evidenced by the predicted *151%* ~~207%~~ increase in the expected number of students by 2060. Law enforcement services show *700 (205%)* ~~nearly 1,400 (213%)~~ additional sworn officers being needed. Library services show *over 2.8* ~~nearly 2.3~~ million volumes would be needed to serve the projected build out population of Riverside County. Similarly, demand for medical services would also be significantly affected, as indicated by the projected *209%* ~~210%~~ increase in the number of hospital beds that would be needed to serve the population of Riverside County at build out. Further, these projections are merely indicators for the overall needs of each public service; for example, to meet the needs of the students projected per Table 5.5-AA, affected primary school districts will need to incrementally add schools, teachers, support staff, etc., for elementary, middle and high school, as the student census increases. Secondary education services and facilities, such as continuing education and adult schools, junior colleges, vocational schools and universities, as well as private schools, specialty schools, etc., will be similarly affected.

For a few public services, current General Plan build out would contribute fewer, but still significant, cumulative increases. These include fire protective services, which have a projected increase in demand of *25%* ~~70%~~ over existing needs. These demands take the form of increased numbers of both people and property needing protection from fires, both urban and wildfires. For fire services, cumulative impacts are particularly significant due to the extensive incremental expansion of urban fringes and rural development into interface/wildland and open, undeveloped areas that are at greater risk for wildland fires (see Section 4.17.2) and also more remote, which results in longer response times and greater difficulty in providing services.

For solid waste disposal *capacity* ~~facilities~~, the projected increase is *also* ~~a much more modest, but still~~ cumulatively significant, *43%* ~~16%~~ over the next 50-plus years. The various waste stream reduction and recycling (diversion) laws enacted by the state and implemented at the county and city level continue to contribute to the lower rates of cumulative increase being projected. Nevertheless, because of existing environmental constraints, landfill siting difficulties and also the long-term environmental impacts inherent in landfill operations (particularly emissions from trucks hauling wastes), EIR No. 441, certified for the current General Plan, found these cumulative impacts to be significant for existing waste disposal facilities.

As shown in the tables above, build out of each of the various General Plan scenarios shown will contribute incrementally to utilization of existing public facilities and demand for additional public facilities and services in Riverside County. On a cumulative basis, the effect of General Plan build out with the project, GPA No. 960, added to it (i.e., the GPU/GPA960 scenario) would generally be *very slightly reduced (1-2%).* ~~incrementally small; an increase of roughly 4% in most cases (3% for fire protection demands).~~ *Compared to the environmental baseline, however, the incremental increases in demand on public services would* ~~In nearly all cases, however, these small, incremental increases would nevertheless~~ be cumulatively considerable due mainly to the constraints upon the County of Riverside's ability to mitigate demands. See impacts, below, for more details. ~~The 1% incremental increase associated with the project projected for solid waste disposal needs is not cumulatively significant.~~

For the cumulative projects (CULM) scenario, ~~similar trends are seen, with~~ most services *would see* ~~seeing~~ an incremental increase of *1-6%.* ~~around 7%. The exception is for fire services, which show only a 3% increase, as this scenario focuses much more of its development within areas of existing and emerging urbanization.~~ For this alternative, all of the projected cumulative impacts would be significant, *particularly* ~~including~~ the increase in demand for solid waste disposal ~~(projected at 6%~~ due to the increased amount of commercial land uses proposed~~)~~.

c. Impacts

Future development will contribute incrementally to cumulative impacts to public services and facilities as Riverside County builds out over time pursuant to the Riverside County General Plan (regardless of scenario). Specific impacts of the severities indicated will include the following:

(1) Fire Protection Services

- Future development would introduce additional people and property requiring fire protection and emergency response services. This would result in additional fire and emergency responses from existing facilities, increasing wear and tear on equipment and necessitating additional facilities and staff. Where the incremental increase in demand exceeds available services, this impact would be cumulatively significant for any of the build out scenarios.

- When new development is located outside the normal radius for acceptable response times, in particular in the urban fringe and wildland areas, additional wildland fire hazards would be created or exacerbated, with people and property at increased risk due to delayed response. In areas without adequate services nearby, this could result in the exposure of people and property to high fire hazard conditions without adequate fire protection.

- Fire and emergency vehicles and equipment responding would experience increased wear and tear due to additional distances traveled. Increased travel times would also decrease the number of calls that could be responded to during a shift. When demand is great enough in a given region, additional fire facilities would be built. However, the provision of additional services would also require financial resources to support additional manpower, equipment and fire stations or other facilities.

- Existing fire facilities may be expanded or new facilities constructed to ensure adequate levels of service and response times. In particular, new fire stations would be needed to serve outlying wildland and urban fringes as growth expands into these areas. In areas where development remains sparse and new facilities are not added, response times may drop below acceptable levels. This impact would be cumulatively significant.

- The construction of new fire stations has the potential to cause adverse environmental impacts in their own right. They will, however, be subject to a number of regulatory measures, Riverside County building codes, CEQA mitigation measures, etc., which should be sufficient to ensure no significant environmental impacts occur. See discussion for Impact 4.17-A in Section 4.17.2.

- Overall, future growth within unincorporated Riverside County, including as a result of GPA No. 960, will substantially contribute to a significant cumulative impact on fire protection personnel, equipment and facilities.

(2) Law Enforcement Services

- New development would introduce additional people and property requiring law enforcement services, including emergency response. This would result in additional routine and emergency responses from existing facilities and create demand for additional facilities and staff. Where the incremental increase in demand exceeds available services, this impact would be cumulatively significant for any of the build out scenarios.

- When new development is located outside the normal radius for acceptable response times, in particular in the urban fringe and wildland areas, hazards related to personal safety and crime would be created or exacerbated, and people and property would be at increased risk due to delayed response. In areas without adequate services nearby, this could result in the exposure of people and property to higher safety hazards and security risks.

- Law enforcement (e.g., County Sheriff Department) vehicles and equipment responding to calls would experience increased wear and tear due to additional distances traveled. Increased travel times would also decrease the number of calls that could be responded to during a shift. When demand is great enough in a given region, additional facilities (i.e., Sheriff Dept. substations) would be built. However, the provision of additional services would also require financial resources to support additional manpower, equipment, substations, correctional facilities, legal/judicial services, etc.

- Existing law enforcement facilities may be expanded and/or new facilities constructed to ensure adequate levels of service and response times throughout Riverside County. In particular, new substations would be needed to serve outlying wildland and urban fringes as growth expands into these areas. In areas where development remains sparse and new facilities are not added, however, response times may drop below acceptable levels. This impact would be cumulatively significant, regardless of build out scenario.

- The construction of new substations has the potential to cause adverse environmental impacts in their own right. They will, however, be subject to a number of regulatory measures, Riverside County building codes, CEQA mitigation measures, etc., which should be sufficient to ensure no significant environmental impacts occur. See discussion for Impact 4.17-B in Section 4.17.3.

- Overall, future growth within unincorporated Riverside County, including as a result of GPA No. 960, will substantially contribute to a significant cumulative impact on law enforcement (e.g., County Sheriff Department) personnel, equipment and facilities.

(3) Solid Waste Management

- The growth population from new residential uses and jobs and economic activity from new commercial, industrial and institutional uses occurring as Riverside County builds out over time would result in a corresponding increase the amount of solid waste generated by these various uses. The disposal of this additional waste would incrementally increase the wastes going into existing landfills, potentially hastening the end of their usable lives, and contribute to the need for new or expanded sanitary landfill facilities.

- Continued growth within Riverside County will incrementally increase the amount of refuse and other solid waste generated, also causing a corresponding increase in the need for disposal services, including hauling, sorting, recycling, ABOP and hazardous materials disposal, as well as an increased need for landfill space. It would also incrementally increase the number (and/or duration) of truck trips occurring within Riverside County for the collection of said wastes.

- The increase in disposal need may hasten existing landfills in reaching their permitted capacity, decreasing their expected lifespan. This incremental contribution of growth, as projected for the proposed project, GPA No. 960, or any of the other General Plan build out scenarios, will result in incremental, but non-substantial, cumulative impacts to existing landfills.

- Continued long-range planning by the Riverside County Waste Management Department will ensure that new disposal facilities (landfills) are developed to meet increasing needs and, in particular, to accommodate the loss of existing landfills as they reach permitted capacity and lifespan. The construction of additional landfills will result in additional incremental environmental impacts in their own right that would be addressed through both existing mitigation (e.g., from this EIR as well as EIR No. 441) and additional mitigation as deemed necessary based on project-specific analyses.

- All future development will be required to comply with all applicable state, federal and county requirements for solid waste disposal, including the Countywide Integrated Waste Management Plan (CIWMP). Accordingly, such development should not interfere with the implementation, attainment or compliance with any of these statutes or regulations. Nor will it cause inconsistencies with applicable statutes and regulations related to solid waste, including the CIWMP.

(4) Schools

- New development will incrementally introduce additional people, particularly schoolchildren, requiring school services within Riverside County. This would result in the need for additional classroom space, as well as teaching and support staff at levels exceeding current capacity. Where increased demand (increased student populations) exceeds available school services and space, impacts will be cumulatively substantial, for any of the General Plan build out scenarios, including that associated with GPA No. 960. Mitigation for such impacts will be provided in accordance with Riverside County Ordinance No. 575 and state law pursuant to the Leroy F. Green School Facilities Act (aka Senate Bill 50), which prohibits local agencies from imposing school impact mitigation fees, dedications or other requirements in excess of those provided by statute. However, to the extent the financial resources generated pursuant to statute are not sufficient to satisfy demand, cumulatively significant school impacts would result.

- Where increases trigger new school facilities or expansion of existing facilities, environmental impacts may occur in association with their construction and/or operation. Adverse environmental impacts would be associated with construction of new school sites/ facilities to the extent their location,

construction methods or operations affect the surrounding area. The construction of additional school facilities, particularly large campuses associated with high schools, have the potential to result in additional cumulatively significant environmental impacts in their own right.

(5) Library Services

- New development will incrementally introduce additional people utilizing library services within Riverside County. This would result in the need for additional library space, reading material and media, as well as librarians and support staff. Where increased demand exceeds available library services, impacts will be cumulatively substantial for any of the General Plan build out scenarios, including that associated with GPA No. 960, if not met with additional services and facilities.

- Mitigation of cumulative impacts to library services will be contingent upon the ability of Riverside County to provide adequate funding and the availability of suitable library sites. Where such financial resources are not sufficient to meet increased need, or where increased service provision lags behind the incremental increase in demand, cumulatively significant impacts to library services will result.

- Where increases trigger the need for new libraries or the expansion of existing facilities, environmental impacts may occur in association with their construction and/or operation. However, due to the relatively small footprints typically associated with libraries, their typically centralized, urban locations, as well as the potential for existing buildings to be retrofitted as libraries, environmental impacts associated with the construction of new facilities can feasibly be limited to less than significant levels.

(6) Medical Facilities and Services

- New development will incrementally introduce additional people within Riverside County needing a wide range of health and medical services. This would result in a corresponding increase in the need for additional medical facilities, including community clinics, hospitals, mental health services, specialty services, skilled nursing facilities, rehabilitation units, pharmacies, imaging and diagnostic laboratories and services, public health services, etc., as well as the skilled staff needed to operate them. Where increased demand exceeds available services, impacts would be cumulatively substantial for any of the General Plan build out scenarios, including that associated with GPA No. 960, if not met with additional services and facilities.

- Mitigation of cumulative impacts to Riverside County medical services will be contingent upon the ability of Riverside County to provide adequate funding and the availability of suitable sites. Where such financial resources are not sufficient to meet increased need, or where increased service provision lags behind the incremental increase in demand, cumulatively significant impacts will result. This may be particularly true for remote, rural or other underserved areas distant from existing major medical centers.

- Where increases trigger the need for new or expanded medical facilities, environmental impacts may occur in association with their construction and/or operation. For community clinics and other smaller scale facilities, the relatively small typical footprints and their typically centralized, urban locations, as well as the potential for retrofitting of existing buildings, environmental impacts associated with the construction of new medical or health facilities can feasibly be limited to less than significant levels.

- For major medical centers that will be needed to serve growing regions, however, adverse environmental impacts would be associated with construction of new facilities to the extent their location, construction

methods and operations affect the surrounding area. Thus, the large campuses typically associated with major medical centers have the potential to result in additional significant environmental impacts in their own right.

d. Mitigation

As described in detail in Section 4.17, a variety of measures would be implemented to avoid, reduce and minimize adverse cumulative impacts to public services and facilities. These include the following:

(1) Regulatory Compliance

Key Regulations and Programs: See Section 4.17.3 for details on each regulation.

- California Government Code, Section 51178: Fire safety standards
- California Building Code, PRC Sections 4290-4299: Addressing fire safety
- California Integrated Waste Management Act: Solid waste diversion regulations
- Assembly Bill 341 (Chesboro, 2011): Solid waste diversion regulations
- Leroy F. Greene School Facilities Act (SB 50): School development fee requirements and limits on CEQA mitigation (CGC Section 65995, in particular)
- County Integrated Waste Management Plan
- Riverside County Fire Protection Master Plan
- Riverside County Ordinance No. 659 - Development Impact Fees Program
- Riverside County Ordinance No. 787 - Fire Code Standards
- Riverside County Conditions of Approval (developed and issued on a project-by-project basis to address the specific project's effects)

Key General Plan Policies: See Section 4.17 for the text of each policy.

- Land Use Element Policies: LU 5.1, 5.2, 7.8, 10.1 and 31.2
- Safety Element Policies: S 5.1-5.9, 5.11, 5.12 and 5.14-5.21

(2) CEQA Mitigation

Existing Mitigation Measures: EIR No. 441, which was prepared and certified for the 2003 RCIP General Plan, contains a number of mitigation measures (MMs) imposed to reduce, avoid or minimize significant impacts related to various public facilities. Since these MMs were programmatic in nature, they remain applicable to this project (GPA No. 960) as well as potentially to any other future development occurring in Riverside County over time.

- **Existing MM 4.15.2A:** The County [of Riverside] shall require as a part of the development review process, proponents of new businesses, recreational and commercial land uses such as shopping centers, health clubs, large hotels over 200 rooms, convention centers and commercial recreational activities to provide onsite security.

- **Existing MM 4.15.2B:** The TLMA [County Transportation and Land Management Agency] shall inform the Riverside County Sheriff's Department of the existence of all new homeowner's associations within the county. The Riverside County Sheriff's Department shall coordinate with homeowner's associations to establish a Neighborhood Watch Program.

- **Existing MM 4.15.2C:** Riverside County shall meet and maintain a goal of 1.5 sworn officers per 1,000 population, as recommended by the International City Managers' Association.

- **Existing MM 4.15.2D:** The County [of Riverside] shall require the development applicant to pay the County Sheriff's established development mitigation fee prior to issuance of a certificate of occupancy on any structure as they are developed. The fees are for the acquisition and construction of public facilities.

- **Existing MM 4.15.3A:** Riverside County shall work with its franchise hauling companies to expand curbside and commercial recycling services throughout the unincorporated area of the county.

- **Existing MM 4.15.3B:** Riverside County shall follow State [of California] regulations in implementing the goals, policies and programs identified in the Riverside County[wide] Integrated Waste Management Plan in order to achieve and maintain a 50% reduction in solid waste disposal through source reduction, reuse, recycling and composting.

- **Existing MM 4.15.3.C:** In accordance with State [of California] regulations, Riverside County shall prepare an annual report of progress for the CIWMB to determine [Riverside] County's progress toward meeting its diversion goals and objectives, to project [Riverside] County's waste disposal needs and to determine if any of the elements that comprise the Riverside CIWMP require revision to include additional disposal capacity, reflect new or changed local and regional solid waste management issues, or reflect new or changed goals and objectives.

- **Existing MM 4.15.3D:** In accordance with CCR Section 18788, Riverside County shall review the Riverside CIWMP every five years to determine if [Riverside] County's waste management practices remain consistent with waste diversion goals and objectives and to assess if revision is required.

- **Existing MM 4.15.3E:** The County [of Riverside] shall require all future commercial, industrial and multifamily residential development to provide adequate areas for the collection and loading of recyclable materials (i.e., paper products, glass and other recyclables) in compliance with the State Model Ordinance, implemented on September 1, 1994, in accordance with AB 1327, Chapter 18, California Solid Waste Reuse and Recycling Access Act of 1991.

- **Existing MM 4.15.3F:** The County [of Riverside] shall require all development projects to coordinate with appropriate [Riverside] County departments and/or agencies to ensure that there is adequate waste disposal capacity to meet the waste disposal requirements of the project, and the County [of Riverside] shall recommend that all development projects incorporate measures to promote waste reduction, reuse, recycling and composting.

- **Existing MM 4.15.6A:** Riverside County shall provide a minimum of approximately 0.5 square foot of library space and 2.5 volumes per county resident.

- **Existing MM 4.15.7A:** Riverside County shall perform a periodic medical needs assessment to evaluate the current medical demand and level of medical service provided within each Area Plan. A periodic medical needs assessment shall be conducted every three years.

- **Existing MM 4.15.7B:** Riverside County shall fund the new construction and/or expansion of existing medical facilities according to the level of demand for medical services. The level of demand would be based on and determined by the outcome of the periodic medical needs assessments.

e. Significance

Implementation of all of the above regulations, General Plan policies and mitigation measures, would help reduce, avoid or minimize the various cumulative impacts to public services and facilities. However, while public service impacts associated with the project, GPA No. 960, are *individually* less than significant, for some public services, incremental impacts will remain *cumulatively* substantial, even with the implementation of all feasible mitigation. Specifically, incremental increases in demand for fire protection and law enforcement services, schools, libraries and medical services will be cumulatively significant under any of the build out scenarios examined herein, including the project (GPA No. 960). Due to the continued implementation of waste diversion and other measures, as well as effective long-range planning and the stable funding of its programs, the incremental contribution of future development arising from the project's General Plan changes would not result in cumulatively significant impacts on existing or future landfills.

17. Cumulative Effects on Transportation and Circulation

Section 4.18 (Transportation and Circulation) evaluates the potential for the project, GPA No. 960, to affect or be affected by the circulation network and transportation within unincorporated Riverside County, as well as its municipal areas (cities) and adjoining jurisdictions (Orange County, San Bernardino County, etc.). This analysis includes assessment of the functionality of both the existing and proposed circulation networks (freeways, expressways, highways and the arterial roadways) within Riverside County. For procedural reasons related to the standard methodology used for traffic studies, the section also addresses cumulative traffic impacts, both directly and tangentially (as traffic is an *inherently* cumulative problem). It also analyzes the mitigation (both through regulatory compliance and EIR mitigation) necessary to ensure impacts are less than significant or mitigated to the extent feasible. Areas already covered in Section 4.18 are not repeated here; see section directly for additional resource details.

Section 4.18 of this EIR provides a description of the existing circulation (roadway) network within Riverside County, as well as modeling existing and future circulation (traffic) impacts projected to occur as Riverside County builds out over time. In total, the circulation networks for both freeways and expressways (generally divided roads with controlled entries and exits) and for arterial roadways (generally county, city and private roads, though not exclusively), five scenarios were modeled and mapped, as per below. Modeling performed for these analyses by the Riverside County Transportation Department used the Riverside County Traffic Analysis Model (RIVTAM). See Appendix EIR-4, section D, for RIVTAM validation report (correlating actual traffic counts to RIVTAM model output).

- **Baseline:** Traffic counts and volumes for base year 2007 as modeled by the Riverside County Transportation Department in RIVTAM and validated with actual roadway counts for the arterial

network and uses Caltrans "Traffic Volumes on California State Highways, 2009" for freeways and expressways. See Tables 4.18-D and 4.18-E in Section 4.18, plus Figures 4.18.1(1-21) through 4.18.5(1-21) in Appendix EIR-4, Section E, for data. Note: This scenario is equivalent to the "Existing Conditions" scenario used throughout the rest of this cumulative analysis section.

- **Baseline Plus Project**: Per Section 4.18, this scenario is the "existing land use and roadway network for all locations outside of Riverside County boundaries (e.g., within cities) and build out of GPA No. 960 land use and roadway network for all County of Riverside facilities." When the 2003 General Plan build out results are added to it, it is roughly equivalent to the "GPU/GP960" scenario. See Figures 4.18.11 through 4.18.14, plus volume and LOS data for Baseline versus Baseline Plus Project in Figures 4.18.15 (1-21) and 4.18.16 (1-21), respectively.

- **2003 General Plan:** This scenario depicts traffic conditions expected upon build out of the existing (defined as 2003 in section 4.18) General Plan and build out of the cities' as well, that is, essentially the without-project (or "status quo") scenario. For data for this scenario, see Figures 4.18.17(1-21) through 4.18.21(1-21). [Note: This scenario is roughly equivalent to the "Current General Plan" build out scenario used elsewhere in this cumulative analysis section.]

- **GPA No. 960 Build Out:** The General Plan circulation network as updated pursuant to the changes proposed under GPA No. 960 at build out. Per Section 4.18, this scenario "represents build out of GPA No. 960 plus build out of all cities land use and roadway network." Thus, it is roughly equal to the project "delta," that is difference between existing and with-project build out conditions. See Figures 4.18.22 (1-21) through 4.18.27 (1-21), in particular Figure 4.18.23 (1-21) which shows the proposed network changes by Area Plan.

- **Cumulative Growth:** This scenario depicts the cumulative General Plan as outlined at the beginning of Section 5.5. That is, it encompasses the additional proposed GPAs as well as the project and is consistent with the "CULM" scenario used throughout this section. See Figures 4.18.28(1-21) through 4.18.31(1-21).

Each of the above figures consists of a set of 21 individual maps depicting the modeling results indicated by Area Plan. For each scenario data included directional daily volumes for freeways and expressways, as well as for the arterial network. Level of service results were also mapped similarly for both types of network. Due to their voluminous nature, all of the exhibits for Section 4.18 are included in the accompanying technical appendix (specifically, Section E of Appendix EIR-4). Additional figures accompanying Section 4.18 (also in Appendix EIR-4.E) include: Figure 4.18.6 (Western Riverside County Park-And-Ride Locations), Figure 4.18.7(1) (Riverside Transit Agency System Map), Figure 4.18.7(2) (SunBus System Map), Figure 4.18.8 (Metrolink Routes Map), Figure 4.18.9 (Riverside County Trails and Bikeway System) and Figure 4.18.10 (Public Airports in Riverside County). Lastly, Figure 4.18.32 (1-21) shows Metrolink service by Area Plan, and Figure 4.18.33 (1-21) does the same for bus rapid transit and express bus routes. All of the above figures are encompassed in technical appendix EIR-4, Section E. A general, countywide overview map of the circulation network can be found in the General Plan, Figure C-1, with detailed maps presented in the Area Plans.

In addition to spatial data, the section includes a number of tables as well: Table 4.18-A (Uninterrupted Traffic Flow Facilities Level of Service), Table 4.18-B (Interrupted Traffic Flow Facilities Level of Service), Table 4.18-C (Segment Volume Capacities/Level of Service for Riverside County Roadways), Table 4.18-D (Baseline Roadway Levels of Service for Freeways and State Routes), Table 4.18-E (Baseline Roadway Levels of Service for Roadway Segments One-mile or Greater (Arterial Road Network)), Table 4.18-F (Daily Truck Volumes on Freeways in Riverside County (Bi-Directional)), Table 4.18-G (Population, Household, Employment and Trip Generation

Comparison), Table 4.18-H (Vehicle Miles Traveled [VMT] Summary), Table 4.18-I (Vehicle Hours Traveled [VHT] and Average Travel Speed Summary), Table 4.18-J (Baseline and Baseline Plus Project (County Growth) Freeway and State Route Segment Levels of Service [LOS]), Table 4.18K (Baseline and Baseline Plus Project Roadway Comparison for Segments One Mile or Greater (Arterial Road Network)), Table 4.18-L (Baseline to GPA No. 960 Freeway and Expressway Comparison), Table 4.18-M (Baseline to GPA No. 960 Comparison for Segments One Mile or Greater (Arterial Road Network)), Table 4.18-N (Summary of Operating Characteristics – Miles of Roadways, Arterial Road Network), Table 4.18-O (Summary of Operating Characteristics – Lane Miles of Roadway, Arterial Road Network), Table 4.18-P (Matrix for Comparing Scenarios and Impacts (County Roads)), Table 4.18-Q (Matrix for Comparing Scenarios and Impacts (City Roads)) and Table 4.18-R (Mitigation Recommendations for GPA No. 960 (Build out)).

a. Existing Conditions

Vehicular Circulation and Roadway Network: Due to the interrelationship of urban and rural activities (employment, housing and services), and the low average density of existing land uses, the private automobile is the dominant mode of travel within Riverside County. Mass transit travel currently represents less than 2% of all trips made in Riverside County. Public transportation, where service is available, is utilized primarily by a transit-dependent population (senior citizens, students, low-income residents and the physically disabled) that generally do not have access to automobiles. Riverside County's industrial and agricultural economies depend on safe and efficient goods movement. Thus, the County of Riverside maintains an extensive network of low volume rural roads in sparsely settled areas to service goods movement and the agricultural industry across the nearly 200-mile expanse of Riverside County. Large trucks are the primary means of transporting such goods, with freight rail forming the critical backbone of the goods movement industry in Riverside County.

Riverside County is linked to Los Angeles and Orange counties principally by State Route (SR) 60 (Pomona freeway), Interstate 10 (I-10) (San Bernardino freeway), SR-91 (Riverside freeway) and SR-74 (Ortega highway). Interstate 15 (I-15) plus minor conventional highways (SR-79, etc.) provide southern links to San Diego County. To the north, links to San Bernardino County in the west are provided by I-15 and I-215, as well as by other major and minor local roadways. To the east, the I-10 freeway provides a connection to destinations in Arizona; I-15 and I-215 provide access through San Bernardino County to Nevada, including its primary recreation areas associated with Las Vegas and Lake Mead. In addition, the I-15 also provides access south to San Diego and its many tourist and recreational amenities, and to Mexico via I-5 and I-805.

The internal highway system includes numerous county roadways, as well as roadways within each of the 29 cities in Riverside County. These major roadways include Alessandro Boulevard, Cajalco Road, Center Street, Domenigoni Parkway, Grand Avenue, La Sierra Avenue, Magnolia Avenue, Monterey Avenue, Murrieta Hot Springs Road, Palm Drive, Ramon Road, Ramona Expressway, Rancho California Road, Temescal Canyon Road, Van Buren Boulevard, Washington Street and others.

To gauge the effectiveness of a given roadway within Riverside County's network, several metrics are used including "Level of Service" (LOS), a key measure of facility capacity. The 2010 Highway Capacity Manual (HCM) (5th Edition) defines the term Level of Service (LOS) as "a quantified stratification of a performance measure or measures that represent quality of service, measured on an A - F scale, with LOS A representing the best operating conditions from the traveler's perspective and LOS F the worst." Tables 4.18-A and 4.18-B provide lists descriptions of the quality of traffic flow for each LOS for uninterrupted and interrupted traffic flow, respectively.

Accordingly, Riverside County has established daily traffic volume range breaks for Circulation Element roadways to correspond to the various levels of service (A-F) for each facility type, consistent with the 2010 Highway

Capacity Manual. See Table 4.18-C of Section 4.18 for this table. The ranges of average daily traffic (ADT) volume described for each roadway facility (collector, arterial, secondary, etc.) at each LOS are intended to provide quantifiable ranges to achieve the qualitative performance outlined in the two tables mentioned above.

Thus, performance of the existing roadway system in Riverside County was analyzed by evaluating key roadway segments in terms of daily traffic volumes (either through direct roadway counts or modeled data), facility characteristics and levels of service. Figures 4.18.1 through 4.18.5 (including subfigures 1 through 21 for each representing each of the Area Plans within Riverside County), located in Appendix EIR-4, Section E, provide specific information related to existing roadway network, traffic flow, traffic volumes and level of service.

According to the analysis presented by the Riverside County Transportation Department in Section 4.18, they determined that the majority of Riverside County's roadway and highway system operate at LOS D or better. This means that motorists on most roadways do not experience substantial delays, even during peak travel hours, and roadway segments are generally operating under capacity. Some roadway and highway segments within Riverside County, however, are heavily congested. Table 4.18-D of Section 4.18 identifies segments of interstate and state routes identified by Riverside County Transportation where the daily traffic volumes indicate LOS E or F conditions. In addition, as indicated in Table 4.18-C, the Transportation Department also notes that under existing conditions, there are a number of interstate and state route segments in Riverside County that operate at or over capacity (e.g., LOS E or LOS F).

Using the Transportation Department's proposed levels of service (i.e., Table 4.18-B), Section 4.18 finds that the only major freeway operating at or below capacity along its entire length through Riverside County is the I-10. The other major freeways (I-15, I-215 and SR-60) only operate at or above capacity on certain segments in Riverside County (others operate within acceptable ranges). For example, SR-91 operates at LOS F between the Orange County line and its junction with SR-60/I-215 in the City of Riverside. Non-freeway state routes that also operate at or over capacity include: SR-62 between Indian Avenue and the San Bernardino County line (LOS F), SR-74 through Lake Elsinore (LOS F) and west of Hemet (LOS E) and SR-111, which hits LOS E on several segments in the Indian Wells/Palm Desert area. All other freeways and State routes have daily traffic volumes that indicate LOS D or better.

Park-and-Ride Facilities: Park-and-ride facilities provide resources that encourage increased vehicle occupancy, which reduces the number of vehicles using roadways and highways in Riverside County. In western Riverside County, nine park-and-ride facilities are operated by Caltrans (with a total of 1,024 parking spaces). The Riverside County Transportation Commission (RCTC) also provides twelve park-and-ride facilities providing 859 spaces, and four private commercial developments provide privately operated park-and-ride facilities providing 320 spaces total. There are no park-and-ride facilities located in eastern Riverside County. See Figure 4.18.6 in Appendix EIR-4, Section E, for location maps.

Public Transit Systems: Fixed-route transit services and demand response (dial-a-ride) transit services are provided by the Riverside Transit Agency (RTA) in the western portion of Riverside County and by the SunLine Transit Agency (SunLine) in the Coachella Valley. According to Section 4.18, RTA operates 36 fixed bus routes, eight commuter bus routes and demand responsive services within a 2,500 square-mile area of western Riverside County. RTA's fixed routes have been designed to establish transportation connections between all the cities and unincorporated communities in western Riverside County and to make commuter connections with transit services in neighboring counties, including OmniTrans in San Bernardino County, OCTA in Orange County and Metrolink (passenger rail) as well. At the end of 2010, RTA operated 97 full-size compressed natural gas buses, 97 dial-a-ride vans, 74 fixed-route vans and ten trolleys. In FY 2010, approximately 7.9 million passengers boarded vehicles operated by RTA, with an average of 26,500 passengers on weekdays and nearly 10,800 on weekend days. All RTA vehicles are wheelchair-accessible, and all full-size buses are equipped with bike racks.

SunLine provides public transit services for the Coachella Valley area, covering approximately 1,120 square miles and homes for about 435,000 residents. As of September 2010, SunLine operated 13 fixed routes with 524 stop locations and served roughly 3.6 million passengers annually. SunLine also operates the SunDial System, providing curb-to-curb demand responsive (dial-a-ride) service. At the end of 2010, SunLine operated a fleet of 125 vehicles, including buses and SunDial vans. In addition to the above, specialized public transportation services are also available through four municipal operators: the cities of Riverside, Corona, Banning and Beaumont. Additionally, the RCTC supports a number of specialized transportation programs including shared ride and vanpool services, social service dial-a-ride and specialized services for seniors and persons with disabilities. The Greyhound Bus Line also provides private transportation services linking the principal population centers of the county with other regions. Existing bus routes are shown in Figure 4.18.7 of Appendix EIR-4.

Waterways and Waterborne Travel: Unlike other parts of the United States, Riverside County does not have navigable waterways providing for significant transport of people and goods between destinations. Water travel is limited to recreational uses in designated regional and local recreational areas.

Passenger / Commuter Rail: Two types of rail passenger services are available in Riverside County: Intercity service provided by AMTRAK and commuter rail service operated by Metrolink. Along rail routes between the West Coast and points east, AMTRAK serves Riverside County at two train stations plus several locations where AMTRAK provides bus links to train stations. In the Coachella Valley, the Palm Springs AMTRAK station provides access to AMTRAK's Texas Eagle and Sunset Limited Services, which provide connections to points west including Los Angeles and to points east including Tucson, Arizona and El Paso, Texas. The downtown Riverside Metrolink/AMTRAK station serves the western portion of Riverside County as a stop along AMTRAK's Southwest Chief Service. The Southwest Chief connects Los Angeles to points east including Flagstaff, Albuquerque, St. Louis and Chicago.

Three Metrolink commuter rail lines serve western Riverside County and provide connections to destinations in Los Angeles, Orange, San Bernardino and Ventura Counties. These three lines are: the Riverside and 91 Lines, which connect downtown Riverside and Union Station in Los Angeles via northern (Ontario) and southern (Orange County) routes, respectively; and, the Inland Empire Line which runs through Riverside as it links San Bernardino to Oceanside in San Diego County. As of December 2010 (most recent data at the time of EIR preparation), five commuter rail stations serve Riverside County: Riverside-Downtown, Pedley, Riverside-La Sierra, Corona-North Main and West Corona. Existing passenger rail routes are presented on Figure 4.18.8 in the Appendix EIR-4.E. Planned commuter rail service (Metrolink) is shown in Figure 4.18.32 (1-21).

Airports and Aviation Services: Palm Springs International Airport, located within the City of Palm Springs, is the only airport within Riverside County providing passenger air service; however, Ontario International Airport in San Bernardino County is located close to the northwestern boundary of Riverside County and provides a convenient travel option for residents of western Riverside County. The County of Riverside owns and operates five public use general aviation airports: French Valley, Hemet-Ryan, Jacqueline Cochran Regional, Chiriaco Summit and Blythe. All but one (Hemet-Ryan) are located within unincorporated territory. As shown in Figure 4.18.10 (in Appendix EIR-4, Section E), a number of other public use general aviation airports are located throughout Riverside County, mainly within cities. A joint use (civilian/military) facility, March Air Reserve Base/Inland Port Airport, is located in Riverside County along Interstate 215 north of the City of Perris. In addition to its military functions, the facility is permitted to accommodate up to 21,000 civilian air flights a year and is expected to expand such operations in the future. The Chocolate Mountain Aerial Gunnery Range (CMAGR) east of the Salton Sea is an extremely active military training facility for fighter jets and other operations, though no formal airport exists on the site. (See Section 4.13 for additional details on military uses.) Existing airport locations are presented on Figure 4.18.10 in the Appendix EIR-4.E.

The Riverside County Airport Land Use Commission (RCALUC) adopts and implements Airport Land Use Compatibility Plans (ALUCPs) establishing criteria for acceptable land uses in the vicinity of airports (known as Airport Influence Areas) to protect and promote the safety and welfare of the residents of the airport vicinity and users of the airports while ensuring the airports' continued operation. Per state law (Public Utilities Code), General Plans must be consistent with ALUCPs unless certain key findings are made by the jurisdiction's decision-makers. A determination of consistency may be subject to conditions of approval recommended by RCALUC for application to the project by the local agency.

Truck Travel and Goods Movement: The primary generators of truck traffic in Riverside County are agricultural and industrial uses. Since agriculture is transitioning to an urban land use pattern in many portions of Riverside County, overall truck traffic volume generated by agricultural uses is expected to decline in the future. However, relocation and replacement of individual agricultural processing plants and other new industries can significantly alter both regional and localized patterns and concentrations of truck traffic in cities and established communities in Riverside County. As healthy industrial growth is expected within Riverside County, industrial truck traffic will continue to increase. Overall, truck trips are expected to increase as Riverside County approaches build out. Currently, trucks comprise at least 15% of the daily traffic volume on some of the primary goods movement corridors in Riverside County: I-15 from Temecula to Ontario, SR-60 westward from I-215 and the I-10 in the Coachella Valley and San Gorgonio Pass areas.

Because of the operational characteristics of trucks, their net effect on traffic flow is two to three times that of an equivalent number of passenger cars on level terrain, and could be considerably more than that on long upgrades, such as I-215/SR-60 eastbound in the Box Springs area and I-10 westbound west of Palm Springs. Traffic engineers describe the effect of trucks in terms of passenger car equivalents or PCEs. Thus, a roadway with 15% truck traffic could be regarded as having lost 30-45% of its capacity to trucks in terms of PCEs. Typically during peak commuting periods, however, the proportion of trucks in traffic is much lower; usually no more than 4-6%. Table 4.18-E in Section 4.18 lists daily truck volumes for selected facilities and locations in Riverside County and Appendix EIR-4, Section C, presents truck traffic volumes on all State of California facilities in Riverside County.

b. Future Conditions

As automotive travel vastly overshadows the other forms of transportation outlined above, the modeling and analyses performed for future conditions focuses on the roadway networks used by motor vehicles in and through Riverside County.

As detailed in Section 4.18, in order to forecast future traffic conditions at the theoretical build out of Riverside County, as well as estimate cumulative build out conditions for the cities within the county, socioeconomic data (SED) was developed by the Riverside County Center for Demographic Research (RCCDR). This data was used to represent the land use build out plans of both Riverside County and its cities. Land use plans were converted to SED using the methodology outlined in General Plan Appendix E-1 (Socioeconomic Build Out Projections, Assumptions and Methodology). This SED development process was used for each of the above scenarios, which were then modeled by the Riverside County Transportation Department via RIVTAM to forecast traffic volumes and other conditions for the various roadway segments studied. The results of these studies are included in Appendix EIR-4.

Table 5.5-AD (Cumulative Traffic Impacts), below, summarizes the cumulative conditions for the three General Plan build out scenarios examined in this section: Existing General Plan (CURR GP), which is the "2003 General Plan" scenario described above; the Updated General Plan as per GPA No. 960 (GP/ GPA960), which is roughly equivalent to the "Baseline Plus Project" scenario above, with the "2003 General Plan" results added to it; and, lastly, the cumulative General Plan as per the additional proposed GPAs through 2009 (CULM GP), the

"cumulative" scenario is presented. Existing conditions (i.e., "Baseline" per above) are also addressed. See Section 5.1 for full details on the specifics for each scenario and Section 4.18 for specifics on the traffic modeling scenarios. It should be noted that the same modeling procedures were used to model each of the build out scenarios.

As noted in Section 4.18, "Figures 4.18.1 [through] 4.18.31 [1-21, respectively] contained in Appendix EIR-4, [Section E] present information related to the analysis scenarios described above, including roadway network assumptions, Metrolink and BRT [bus rapid transit]/ express bus assumptions, traffic flow and levels of service."

As shown in the table below, build out of any of the analyzed General Plan scenarios (including the General Plan as amended per GPA No. 960, i.e., the "GPU/GPA960 scenario") would increase traffic levels as a result of growth and increased development, both in Riverside County and in the cities. These impacts would incrementally contribute to cumulatively considerable traffic volumes and result in significant traffic impacts at affected segments and intersections serving both existing and future uses. As discussed in greater detail in Section 4.18, future development will contribute incrementally to cumulative transportation and circulation impacts as Riverside County builds out (develops) over time pursuant to the Riverside County General Plan.

Table 5.5-AD: Cumulative Traffic Impacts

SCENARIO:	EXIST	CURR GP Build Out		GPU/GPA960 Build Out		CULM Build Out

Source: Riverside County Transportation Department, Section 4.18 (Transportation and Circulation), Tables 4.18-F, 4.18-G and 4.18-H, 2012, and cumulative data from Appendix EIR-4, 2012.

As shown in the table above, each of the General Plan build out scenarios will generate additional population and employment sources, and therefore, additional vehicle trips compared to existing conditions (i.e., the Baseline scenario). According to the analysis presented in Section 4.18 and summarized above, growth resulting from the General Plan changes proposed by GPA No. would increase vehicle trips in Riverside County by 29% over baseline conditions. With no project, continued growth in Riverside County merely according to the existing General Plan (plus build out of the cities) would increase total number of vehicle trips within Riverside County by 119% over baseline conditions. Thus, even though the amount of growth accommodated by the project itself is decreased by 3%, overall countywide trip generation would still increase by a cumulatively considerable amount. When the additional growth proposed under the added GPAs of the cumulative (CULM) scenario is taken into account, future traffic levels increase even further. Thus, traffic impacts under any of the build out scenarios analyzed in this EIR would be cumulatively significant.

In addition to Table 5.5-AD, above, per the County Transportation Department, Tables 4.18-K and 4.18-L in Section 4.18 show some of the "numerous facilities" expected to operate at unacceptable levels of service under the updated (with-project) General Plan (i.e., GPU/GPA960 scenario), "even with the updated policies identified in GPA No. 960," such as the revised LOS ranges. The analysis also finds that the "Baseline Plus Project" build out scenario would "more than double" the miles of roadway that would operate at LOS E or LOS F.

c. Impacts

Future development will contribute incrementally to cumulative traffic, transportation and circulation impacts as Riverside County builds out over time pursuant to the Riverside County General Plan (regardless of scenario). Specific impacts of the severities indicated will include the following:

(1) Cumulatively Considerable Impacts

- Future implementation of the Riverside County roadway network as proposed under GPA No. 960 (GPU/GPA960 scenario) is designed to generally improve traffic conditions throughout Riverside County compared to that projected under build out of the Existing General Plan (CURR GP scenario). This is due to the refined roadway network design (i.e., revisions to better suit developing land use and circulation patterns) proposed under GPA No. 960. However, build out of Riverside County pursuant to the proposed project changes would still result in incremental traffic increases over time that will cumulatively contribute to deficient operations within Riverside County's circulation network, as well as adversely affect certain roadways within the cities of Riverside County, as well as areas outside the county (adjacent cities, counties, etc.). The proposed Circulation and Land Use Element policy changes incorporated into GPA No. 960 will partially address and improve these deficient conditions. However, a number of deficiencies will remain and additional implementation actions (i.e., the specific mitigation measures listed below) are necessary for some facilities to reduce cumulative traffic impacts to less than significant levels. For other transportation facilities, even with additional improvements, not all will be able to be mitigated to less than significant levels (i.e., due to physical, jurisdictional or environmental constraints for example) and will be subject to cumulatively significant unavoidable impacts.

- Future development would incrementally increase rural, suburban and urban uses in Riverside County resulting in new vehicle trips by travelers and commuters in previously little-traveled areas, areas of existing traffic congestion (i.e., currently unacceptable LOS), existing roadways of insufficient size or capacity to accommodate the resultant traffic increases and also new roadways. Incremental effects to these various roadway types, including those within the unincorporated county, its cities, state and federal highways, and adjoining roadways outside Riverside County, regardless of build out scenario, would result

in cumulatively considerable impacts where LOS or other applicable metric is or becomes unacceptable. According to the traffic analysis performed by the Riverside County Transportation Department, Section 4.18 (Transportation and Circulation) notes that, "Of the 153 identified roadways in Table 4.18-L, 99 roadways have mitigation designations recommended for adoption. The remaining 54 roadways require coordination with other jurisdictions and/or are constrained by existing development or environmental considerations." Thus, in locations constrained by existing development, geology, biology or other limiting factors or hazards, Riverside County's ability to fully mitigate such impacts through road widening, signalization and other improvements would be impaired resulting in cumulatively considerable impacts that cannot be mitigated to less than significant levels. Lacking jurisdiction over territory outside Riverside County's boundaries, the County of Riverside would similarly be constrained from fully mitigating to less than significant levels some of the cumulatively significant impacts occurring on roadways outside Riverside County.

- For roadway facilities, existing or future (build out) conditions are defined to have a significant adverse effect on traffic conditions if the roadway segment's Level of Service (LOS) shows operations falling to an unacceptable LOS (typically LOS E or F) as per the applicable adopted LOS targets (e.g., General Plan Figure C-3). As indicated in Section 4.18 (for example, in Tables 4.18-D and 4.18-E), since some roadway segments already operate at unacceptable LOS, additional traffic generated as Riverside County grows over time would further add to congestion, regardless of build out scenario. Tables 4.18-K and 4.18-L in Section 4.18 indicate the roadway segments expected to operate at unacceptable levels of service under the updated General Plan (with-project, i.e., GPU/ GPA960 scenario), "even with the updated policies identified in GPA No. 960," such as the revised LOS ranges.

- As growth occurs within Riverside County and its cities (pursuant to any of the build out scenarios), the increased population and employment sources will result in cumulatively considerable increases in both the vehicle miles traveled (VMT) and the VMT per-capita value (see Table 4.18-G or 5.5-AE). This VMT increase would lead incrementally to additional time spent in traffic by commuters, increased wear and tear on vehicles negotiating the traffic, increased noise and increased emission of air pollutants and greenhouse gases. Because not all roadways operating at (or forecast to operate in the future at) unacceptable standards can be mitigated, the growth associated with this project will incrementally contribute to cumulatively significant impacts on vehicle miles traveled.

- The VMT increases described above would in part be offset over time as new commercial and employment destinations are developed in local proximities for today's more isolated and under-served communities and also would be additional network (roadway) improvements expanding existing capacity and/or providing alternate routes to desired destinations. In these cases, congestion impacts would be temporary, that is limited to the period of use before planned improvements are implemented. Where the LOS change proposed under GPA No. 960 delays the implementation of improvements, growth in Riverside County will incrementally contribute to significant, but short-term, impacts. In most cases, provision of the roadway improvements called for in the proposed Circulation Element roadway networks will be sufficient to bring roadway operations to within acceptable limits. However, where improvements are not possible (i.e., for the reasons outlined in Table 4.18-R), impacts would be long-term rather than short-term, and cumulatively significant and unavoidable, as previously described, for any of the build out scenarios examined.

- Regardless of build out scenario, growth within Riverside County (and even just accounting for the growth that will occur within the cities of Riverside County) will incrementally increase the number of facilities and the total roadway lane-miles within the network over time compared to baseline conditions. The increases will, however, be slightly less for both the GPU/GPA960 and the CULM build out

scenarios compared to build out of the Existing General Plan (CURR GP scenario) due to the network refinements previously noted. Nevertheless, this incremental increase in lane-miles traveled will result in cumulatively considerable impacts for any of the build out scenarios based on the criteria described in Section 4.18.

- Table 5.5-AD indicates that total vehicle miles traveled (VMT) and also VMT per capita will be improved (i.e., decreased) for both the project (GPU/GPA960) and cumulative (CULM) build out scenarios. However, all of the General Plan build out scenarios will result in cumulatively considerable increases in both metrics as compared to existing conditions (EXIST scenario).

- Growth in Riverside County and its cities over time (pursuant to any of the build out scenarios) will also incrementally increase the vehicle hours traveled (VHT) as additional travelers seek to use roads without enough existing and/or future capacity to efficiently carry the new demand. (See Table 4.18-H in Section 4.18 or Table 5.5-AD, above.) The result is an increase in congestion, meaning slower travel times with trips taking longer to cover the same distance. This VHT increase would lead incrementally to additional time spent in traffic by commuters, increased wear and tear on vehicles negotiating the traffic, increased noise and increased emission of air pollutants and greenhouse gases. Per Section 4.18, several factors can influence this measure, such as the presence or absence of alternative travel routes, trip distributions over the course of a day or the way trips balance destinations and direction of travel during a given period of the day (for example, traveling off-peak instead of peak). The project's proposed change in LOS standards would further exacerbate this impact by delaying the point at which mitigation may be triggered (warranted) for new development contributions to additional traffic. For example, VHT values (and the associated cumulative impacts) will remain high if it takes longer to trigger a road's necessary congestion-alleviating improvements scheduled under the General Plan.

- Not all roadways will achieve acceptable levels of service as called for by the RCTC Congestion Management Plan (CMP) for Riverside County. As noted in Table 4.18-R, even with mitigation (including planned improvements), not all roadway segments can achieve acceptable levels of service. Where roadways addressed under the CMP cannot be brought up to operating within the standards deemed acceptable by the CMP, said roadways will conflict with the achievement of the CMP's objectives. This inconsistency will be cumulatively considerable for the circulation facilities at issue for any of the build out scenarios addressed.

(2) Non-Substantial Incremental Impacts

- Future growth within Riverside County as a result of any of the General Plan build out scenarios will contribute incrementally to changes in air traffic patterns, including increases in air traffic at some airport locations and expansion of air services or facilities at some airports. The increase or expansion of air operations will incrementally increase the areas potentially at risk from air-related safety hazards. Such incremental increases, however, would be non-substantial and would not be cumulatively significant. Further, no new airports or expansions are included in GPA No. 960.

- Future growth within Riverside County as a result of any of the General Plan build out scenarios will contribute incrementally, but non-substantially, to increased demand for rail and air travel and increased use of these systems. Waterborne travel effects will be minimal (and not individually or cumulatively significant) as recreational water uses are the only type occurring in Riverside County; there are no navigable waterways used in Riverside County. Any incremental increases in usage that would occur in association with GPA No. 960 would be non-substantial and not cumulatively significant. Further, no new air, rail or water facilities are included in GPA No. 960.

- Future growth within Riverside County as a result of any of the General Plan build out scenarios will also contribute incrementally to increases in road hazards due to design issues or incompatible uses. These incremental hazards, however, will be avoided, reduced or minimized to cumulatively less-than-significant levels through adherence to Riverside County Transportation design, engineering, construction, operation and maintenance standards.

- Future development would introduce new uses that require both new roads and, in some locations, improvements to existing roads. The construction of such roads would result in temporary traffic impacts to existing roads due to lane closures or narrowing, equipment encroachments, delays, detours, increased traffic on alternate routes and other effects. Due to their temporary nature, however, these construction impacts are generally do not rise to the level of cumulatively considerable.

- Roadway improvements to existing roads plus the addition of new roads will incrementally increase the need for and demand upon roadway maintenance. Such increases will not be cumulatively significant, however, according to Section 4.18. As indicated under Impact 4.18.F, a process exists that will ensure that proper road maintenance is supported by the demand levels which contribute to maintenance revenue, making the impact less than significant for GPA No. 960.

- Future growth within Riverside County (pursuant to any of the build out scenarios, including the with-project GPU/GPA960 scenario) will trigger roadway improvements and new road construction that will have short-term, non-substantial cumulative impacts on portions of the roadway network and the travelers that use it. Section 4.18.5 notes that since GPA No. 960 includes adequate policies to ensure construction-related-impacts are reduced, "traffic circulation [will be] maintained and impacts... maintained at less-than-significant levels." Use of the Riverside County Transportation Improvement Plan (TIP), in particular, to establish and prioritize the timing and construction of Riverside County roadway projects will ensure such cumulative impacts are less than significant.

- Where incremental traffic increases cause roadway segments to operate below applicable standards, the resultant congestion could indirectly affect the safety and well-being of residents and visitors to Riverside County by delaying response times for emergency services, such as ambulances, fire trucks and law enforcement. Similarly, delays to trucks and other goods movement could slow delivery schedules and increase the cost of shipping through greater fuel consumption. These delays, however, are not expected to be cumulatively considerable overall for GPA No. 960.

- Similarly, increased traffic congestion, reduced operating levels and construction impacts would also incrementally contribute to inadequate emergency access at times for any of the build out scenarios. Such incremental increases will be non-substantial and not cumulatively significant however, as GPA No. 960 incorporates policies to ensure adequate emergency vehicle access according to Impact 4.18.H in Section 4.18.5.

- Where incremental traffic increases cause roadway segments to operate below applicable standards, the resultant congestion could result in delays to mass transit services (namely, buses), which would delay commuters' transit times and possibly cause fare increases to cover increased fuel costs (if passed on to customers). These delays, however, are not expected to be cumulatively considerable overall for GPA No. 960.

- Future growth within Riverside County as a result of any of the build out scenarios, including the with-project GPU/GPA960 scenario, will incrementally increase the demand for and use of public transit, bikeways and pedestrian facilities. These increases will not be cumulatively considerable, however,

because, as pointed out in Impact 4.18.I in Section 4.18.5, GPA No. 960 incorporates policies to ensure adequate transit, bicycle and pedestrian facilities. These policies will also ensure that the performance and safety of such facilities are likewise maintained. Therefore this cumulative impact is considered less than significant.

d. Mitigation

In general, the revisions to the Riverside County roadway network are designed specifically to alleviate unacceptable operating levels. Thus, the principle form of "mitigation" for many of the roadway traffic impacts discussed above and in Section 4.18 is to construct new roads and improve existing roads to achieve the build out conditions (i.e., number of lanes, signals, locations, etc.) shown in the General Plan Circulation Element network maps, as proposed pursuant to the project, GPA No. 960. However, in addition, as described in Section 4.18.5, a variety of other measures would be implemented to avoid, reduce and minimize adverse cumulative traffic, transportation and circulation impacts. These include the following:

(1) Regulatory Compliance

Key Regulations and Programs: See Section 4.18.3 for details on each regulation.

- State Transportation Improvement Program (STIP)
- California Complete Streets Act - AB 1358 (2008)
- California Global Warming Solutions Act - AB 32 (2006d)
- California Sustainable Communities and Climate Protection Act - SB 375 (2008)
- SCAG 2012 Regional Transportation Plan / Sustainable Communities Strategy (RTP/SCS)
- RCTC Riverside County Congestion Management Program (CMP)
- Riverside County CETAP (Community and Environmental Transportation Acceptability Process)
- County Ordinance No. 413 - Regulating Parking on County Roadways
- County Ordinance No. 452 - Regulating Speed Limits on County Roadways
- County Ordinance No. 460 - Subdivision of Land
- County Ordinance No. 461 - Roadway Improvement Standards and Specifications
- County Ordinance No. 499 - Encroachment on County Roadways
- County Ordinance No. 659 - Development Impact Fee [DIF] for Residential Projects
- County Ordinance No. 671 - Establishing Consolidated Fee Program for Land Use

- County Ordinance No. 673 - Establishing a Transportation Uniform Mitigation Fee [TUMF] Program for the Coachella Valley
- County Ordinance No. 748 - Mitigating Traffic Congestion Through Signalization
- County Ordinance No. 824 - Establishing a Transportation Uniform Mitigation Fee [TUMF] Program for Western Riverside County
- County Ordinance No. 859 - Establishing Water-Efficient Landscape Requirements

Key General Plan Policies: See Section 4.18.2 for the text of each policy.

- Circulation Element Policies: C 1.2, 1.3, 1.7, 1.8, 2.1-2.7, 3.1-3.4, 3.6-3.8, 3.14- 3.17, 3.23, 3.24, 4.1-4.3, 4.6-4.9, 6.3, 6.5, 6.6, 7.1-7.4, 7.7, 7.8, 8.3, 8.4, 8.7, 8.8, 9.1, 9.2, 11.1, 11.6, 12.2, 13.1, 13.3-13.5, 13.7, 14.1, 14.2, 15.1-15.6, 16.1-16.8, 17.1, 17.3, 17.4, 18.1-18.3, 20.1, 20.3-20.16, 21.1-21.7, 23.4-23.9, 25.1 and 25.2
- Land Use Element Policies: LU 14.6

(2) CEQA Mitigation

The following CEQA mitigation measures (MMs) were adopted as part of certification of EIR No. 441 for the RCIP General Plan in October 2003 and remain applicable to GPA No. 960 and future General Plan implementing projects:

Existing Mitigation Measures: In EIR No. 441, a number of mitigation measures were imposed to reduce impacts from existing and future traffic increases. According to Section 4.18.5, these measures remain applicable to this project and would also apply to future development.

- **Existing MM 4.16.1A:** As part of its review of land development proposals, the County [of Riverside] shall require project proponents to make a "fair share" contribution to required intersection and/or roadway improvements. The required intersection and/or roadway improvements shall be based on maintaining the appropriate level of service (LOS D within Community Development Areas designated by the 2002 Riverside County General Plan and within adjacent jurisdictions; LOS C within those portions of unincorporated Riverside County outside of Community Development Areas). The fair share contribution shall be based on the percentage of project-related traffic to the total future traffic.
- **Existing MM 4.16.1B:** As part of its review of land development proposals, the County [of Riverside] shall ensure sufficient right-of-way is reserved on critical roadways and at critical intersections to implement the approach lane geometrics necessary to provide the appropriate levels of services.

New Mitigation Measures: Section 4.18 proposes the following new mitigation measures to help minimize the effect of growth on existing and future roadways. Compliance with these measures would help mitigate significant transportation and circulation impacts.

- **New MM 4.18.1A-N1:** As part of its review of land development proposals, the County of Riverside shall require project proponents to make a "fair share" contribution to required intersection and/or roadway improvements. The required intersection and/or roadway improvements shall be based on maintaining the appropriate level of service (LOS D or better). The fair share contribution shall be based on the percentage of project-related traffic to the total future traffic.

- **New MM 4.18.1B-N1:** As part of its review of land development proposals, the County of Riverside shall ensure sufficient right-of-way is reserved on critical roadways and at critical intersections to implement the approach lane geometrics necessary to provide the appropriate levels of services.

- **New MM 4.18.1C-N1:** Where needed and where appropriate, the County of Riverside shall seek ways and means to increase the capacity of Circulation Element roadways by such measures as adding through-travel lanes or additional turning lanes without increasing the right-of-way width requirement for the classification of the facility.

- **New MM 4.18.1D-N1:** Where needed and where appropriate, the County of Riverside shall collaborate with the California Department of Transportation (Caltrans) and other appropriate agencies to add auxiliary and mainline lanes on the freeway system within available rights-of-way.

- **New MM 4.18.1E-N1:** The County of Riverside shall collaborate with Caltrans and other appropriate agencies to develop direct connections between the HOV/HOT lanes at the following freeway interchanges: I-15 at SR-91, SR-60 at SR-91/I-215 West junction, SR-60 at I-215 East junction, and at other locations as needed. To the extent that such improvements may be possible within existing rights-of-way, environmental impacts would be less than significant.

- **New MM 4.18.1F-N1:** Where appropriate the County of Riverside shall collaborate with Caltrans and other appropriate agencies to develop HOV lanes along the entire length of I-215 within Riverside County and along I-10 between the San Bernardino County line and Indio.

e. Significance

The Circulation Element policies provide a framework for development and implementation of the multi-modal transportation system envisioned by the General Plan, as proposed by the project, GPA No. 960. However, even with the identified policies, numerous faculties will operate at unacceptable levels of service. As outlined above, future development accommodated by any of the General Plan build out scenarios, including that with the project (GPA No. 960), would result in cumulatively considerable increases in traffic levels with related decreases in roadway segments operating at acceptable standards at various locations throughout Riverside County based on both existing and projected traffic volumes and roadway configurations.

As a result, some roadways within Riverside County would also conflict with applicable congestion management plan standards or policies, such as level of service standards and travel demand measures. Implementation of the various regulatory programs and mitigation measures listed above would help reduce the above cumulative impacts, but according to Section 4.18.5, would not be fully sufficient to ensure that all cumulative impacts are reduced to less-than-significant levels. The changes proposed under GPA No. 960 (and included in the GPU/GP960 scenario) serve to reduce the predicted traffic generated and raise the LOS improvement trigger ranges, resulting in a forecast of lower traffic impacts when compared to the existing General Plan (i.e., CURR GP scenario). When compared against the existing environmental conditions (the EXIST scenario), however, the project will still result in cumulatively considerable traffic impacts as a result of General Plan implementation.

For the impacts listed as not considerable, implementation of the regulatory programs, policies and mitigation measures listed above would be sufficient to ensure that incremental impacts are not cumulatively significant. This includes incremental airport, water and rail impacts, road hazards, emergency access deficiencies and effects to non-motorized travel, such as mass transit, bikeways and pedestrian trails.

18. Cumulative Effects on Water Resources

Section 4.19 (Water Resources) discusses existing water resources, including hydrology, groundwater, imported water and infrastructure for both water and sewer. It analyzes demand on existing water supplies, as well as the need for additional supplies to serve future development accommodated by the changes proposed by the project, GPA No. 960, as well as the mitigation (both through regulatory compliance and EIR mitigation) necessary to ensure individual project impacts are less than significant or at least reduced where feasible. As a result, areas already covered in Section 4.19 are not repeated here; see Section 4.19 directly for additional resource details.

As part of its data and analysis, Section 4.19 provides a number of related figures and tables, including: maps of the water districts, watersheds and hydrological regions of Riverside County (Figures 4.19.1 through 4.19.5), areas covered by MS4 permits (Figures 4.19.6 through 4.19.8), master drainage plans (Figure 4.19.9) and groundwater basins (Figure 4.19.14), information and diagrams related to imported water supplies (Figures 4.19.10 through 4.19.13, plus Figure 4.19.25), county water supplies (Figures 4.19.15 through 4.19.17) and wastewater/sewer providers (Figure 4.19.32), as well as service area boundary maps for the water districts serving Riverside County (Figures 4.19.18 through 4.19.24 and Figures 4.19.26 through 4.19.31).

The numerous tables in Section 4.19 include: Table 4.19-A (Summary of Water and Sewer Providers), Tables 4.19-B through 4.19-D on water quality issues, Table 4.19-E (County Master Drainage Plans and Area Drainage Plans), Tables 4.19-F through 4.19-J and 4.19-AT on imported water issues, Table 4.19-K (Adjudicated Waters), Table 4.19-L (Groundwater Basins), Tables 4.19-M and 4.19-N on well data and Tables 4.19-O through 4.19-AA on a variety of data on Metropolitan Water District (MWD), as well as other water districts serving Riverside County: Tables 4.19-AB through 4.19.AD on Eastern Municipal Water District (WD), Tables 4.19-AE through 4.19-AG on Western Municipal WD, Tables 4.19-AH through 4.19-AJ on San Bernardino Valley Municipal WD, Tables 4.19-AK through 4.19-AM on Jurupa Community Services District, Tables 4.19-AN through 4.19-AP on Rubidoux Community Services District, Tables 4.19-AQ through 4.19-AW on Coachella Valley Water District, Tables 4.19-AX through 4.19-AZ on Desert Water Agency, Tables 4.19-BA through 4.19-BB on San Gorgonio Pass Water Agency, Tables 4.19-BC through 4.19-BE on San Jacinto Mountain Area, Table 4.19-BF (Groundwater Basins Underlying Non-Served Areas), Table 4.19-BG (Sewer and Wastewater Treatment Providers) and Table 4.19-BH (Wastewater Treatment Facilities). In addition, Tables 4.19-BI through 4.19-BN address various calculations and comparisons for theoretical water supplies and wastewater generation for the project and other scenarios. Lastly, Tables 4.19-BO through 4.19-BQ address spatial effects to hydrology, groundwater basins and master drainage plans within Riverside County.

a. Existing Conditions

Historically, water supply issues have been of critical import to California, in general, and interior counties like Riverside County, in particular. Factors, such as hydrology, distribution system capacities, competing demands and regulatory constraints, all present enormous challenges. Capturing and storing water in above-normal years for use in below-normal years remains critical to water supply sufficiency, as does ensuring adequate infrastructure, storage and conveyance facilities.

As set forth in Sections 4.19.3 and 4.19.4, the State of California (via the State Water Project), as well as wholesale and retail water agencies throughout Riverside County, maintain and carefully manage diversified water supply portfolios of imported supplies, local surface water supplies, groundwater, recycled water, desalinated supplies, etc. As detailed in Section 4.19.4, the water demands associated with Riverside County (regardless of the General Plan build out scenario proposed) are ultimately part of demands that are forecast and accounted for by the relevant wholesale and retail agencies. As EIR No. 521 is a programmatic document covering a number of countywide issues, and not does not propose or implement any specific development, only a "first tier" water

supply analysis is presented in Section 4.19. Future development will still be required to prepare/obtain any water supply analyses required by law when specific proposals are made.

Hydrology: For planning, analytical and other specified purposes, the California Department of Water Resources (DWR) organizes the state into ten major surface water drainage regions, two of which (the South Coast Region and the Colorado River Region) include portions of Riverside County. Detailed information and analyses have been prepared for these regions by DWR and that information is updated on an ongoing basis as part of the California Water Plan update process. Generally, the western one-third of Riverside County lies within the South Coast Region, west of the San Jacinto Mountains, and the eastern two-thirds of Riverside County lie within the Colorado River Region. Designated watershed areas are included within each region, several of which partially lie within Riverside County. Figure 4.19.3 shows the major watersheds as they fall within Riverside County. Additional information about the conditions existing in these watersheds is provided in Section 4.19.2.

Topographically, most of the South Coast Region is composed of several large, undulating coastal and interior plains. The coastal and interior valleys of the South Coast Hydrologic Region feature Mediterranean climates characterized by mild, wet winters and warm, dry summers. Roughly 40% of the South Coast Region is developed with urban or suburban uses. Although agricultural land uses remain important in the region, such uses are increasingly giving way to urbanization. Of the total water supply to the region, more than half is used by native vegetation, evaporates to the atmosphere, is used for agricultural crops and managed wetlands, or flows to other states, the Pacific Ocean and salt sinks, like saline groundwater aquifers. The remaining portion, identified as consumptive use of applied water, is distributed among urban and agricultural uses, or diverted to managed wetlands. Figure 4.19.4 shows the South Coast Hydrologic Region.

The major water course in the American Southwest, the Colorado River spans six states and stretches into Mexico. It is controlled by a number of dams along its length, including Parker Dam, which is the origin point for the Colorado River Aqueduct, which runs west and south to its terminus at Lake Mathews in western Riverside County. Once water enters the lower Colorado River mainstream, its use is subject to the "Law of the River," a collection of laws, regulations and agreements that dictate how and where Colorado River water is distributed (see Appendix EIR-8 for more information). The Colorado River also forms the eastern-most boundary of the County of Riverside. Within the county, the Colorado River basin extends from the eastern slopes of the San Bernardino and San Jacinto Mountains east to the state border. California's largest inland body of water, the Salton Sea, lies within this region. Figure 4.19.5 shows the Colorado River Hydrologic Region.

Water Quality: Water quality is an ongoing core issue for nearly all the watersheds and groundwater basins in Riverside County. Non-point source pollution control, salinity management and emerging contaminants are all key water quality issues. In urban areas, population and economic growth not only affect water demand, but add contamination challenges from increases in wastewater and industrial discharges and urban runoff. In rural areas, failing septic systems, agricultural chemical usage and livestock operations contribute to local surface water sediment and contamination from disturbed areas. In the South Coast Region, surface and groundwater salinity (i.e., total dissolved solids, TDS) are an ongoing challenges, particularly as reclaimed water and groundwater recharge become increasingly important for urban water supplies. Groundwater contamination from industrial uses and other sites (such as the infamous Stringfellow Acid Pits) in the form of volatile organic compounds (VOCs) and heavy metals, in particular, is another water quality concern in the region. In the Colorado River Region, the highest priority water quality issues include: the need for surface water quality monitoring, the quality of imported water, the need for onsite treatment systems, high nitrate levels, leaking underground storage tanks and impacts from animal feed lots and dairy operations. The Salton Sea remains a particular challenge for the region due to its extremely high TDS concentration (about 40% saltier than ocean water).

Statewide (Imported) Water Supplies: Like more than two-thirds of California's residents, much of the drinking water used by Riverside County residents is supplied by the State Water Project (SWP), which delivers water originating from the San Francisco-San Joaquin Bay-Delta (the Delta) and is operated by the California DWR. See Figure 4.19.10. The SWP's water supply capability depends on rainfall, snowpack, runoff, reservoir storage, pumping capacity from the Delta and legal environmental constraints on project operations. Its water supply comes primarily from storage at Lake Oroville (fed from the Sierra Nevada Mountains) and high runoff flows in the Delta, with water deliveries that have ranged from 1.4 million acre-feet (AF) in dry years to roughly 3.7 million AF in wet years.

On an annual basis, the DWR establishes SWP water allocations to State Water Contractors (SWCs) according to a variety of factors, including watershed status (i.e., the amount of rain and snow water expected), environmental needs, contractual water rights and other factors which are discussed in detail in Section 4.19.3. The end result is the release of a delivery reliability report that forecasts SWP water yields. It is important to note that even with water contracts outlining how much water a SWC is "entitled" to each year, these "entitlements" only quantify the *maximum* SWP water each contractor can expect. They do not guarantee water delivery. This variability and year-to-year uncertainty lies at the heart of many of Southern California's ongoing water supply issues. Tables 4.19-G and 4.19-H in Section 4.19.3 outline the contractual water delivery amounts associated with the State Water Contractors that serve Riverside County. Table 4.19-J details regional water balance data and Section 4.19.3.D details factors affecting water delivery reliability according to the 2011 State Water Plan Final Delivery Reliability Report. Issues affecting reliability include water availability at the source (including droughts), water rights and priorities, regulatory restrictions on SWP Delta exports (delta smelt protections, adaptive management needs, etc.), climate change effects and infrastructure limitations (levee failures, etc.).

Water imported from the Colorado River is regulated pursuant to a complicated mixture of statutes, contracts and regulations that date back over 100 years. Chief among these is the 2003 Quantification Settlement Agreement (QSA) executed by Imperial Irrigation District (IID), CVWD and MWD. The QSA establishes the baseline Colorado River water use for each of the agencies and facilitates the transfer of water from agricultural agencies to urban uses.

Local Water Supplies: While imported water makes up a large portion of the region's supply of drinking water, local sources are an important part of the overall water resources for Riverside County. The chief source of local water supplies is groundwater, which is discussed in detail in Section 4.17.4.B for groundwater basins in Riverside County. Other local sources of water include surface water (rivers, streams, etc.) and recycled water (such as that reclaimed from wastewater treatment plants, among others), as well as desalination, graywater and other less-prominent sources.

Section 4.17.4 also includes detailed descriptions of the water supplies, services and resources associated with each of the water agencies that serve Riverside County. A particular emphasis is given to the Metropolitan Water District of Southern California (MWD), since it is the major water importer and wholesale supplier serving most of Southern California, including most of western Riverside County. Following MWD, descriptions are provided for the other large wholesale water agencies serving Riverside County, first for western Riverside County and then for eastern. Accompanying these are brief descriptions of the individual retail water providers that rely on these wholesalers. Details on the wholesale water districts include topics such as each district's water supply sources (imported, groundwater, recycled, etc.), amounts, reliability, infrastructure and contingency plans. Forecasts for water supply and demand (typically from 2010 to 2035 as per Urban Water Management Plan requirements) and various water-year budgets (average year, single dry year, multiple dry years) are also included. Lastly, the sufficiency of planned supplies are summarized. For agencies that have (retail) subagencies and/or provide wastewater (sewer) treatment services, these are also briefly detailed. Areas that lie outside of the service areas of

existing water agencies are also detailed in Subsection 4.19.4.I according to the underlying groundwater basin that would by necessity would be used.

Wastewater and Sewer: As noted above, a number of water districts also provide sanitary sewer and wastewater treatment services. For the rest of Riverside County, individual properties rely on individual septic systems for sewage disposal where sanitary sewer connections to a wastewater treatment provider are not available. Wastewater, sewer and septic system issues are discussed in detail in Section 4.19.4.J.

b. Future Conditions

Over time, ongoing growth will increase the amount of people, property, structures and new uses in Riverside County, which will generate additional demand for water supplies, sewer disposal and wastewater treatment. New development, particularly in previously undeveloped, vacant areas, such as wildlands and fringe areas, will also affect existing hydrology and require additional water services, such as treatment, pumping and conveyance facilities for potable water and wastewater, as well as storm drainage, etc. The tables below indicate the relative scope of cumulative impacts to supplies, demand and infrastructure for both water and sewer (wastewater) expected in Riverside County. Cumulative impacts to other water resources issues, such as water quality and hydrology, are addressed qualitatively in the subsequent *sub*section.

Table 5.5-AE (Cumulative Effect on Theoretical Potable Water Demand) provides a summary of demand for potable water within the County according to theoretical estimates associated with existing land uses, as well as for each of the General Plan build out scenarios listed. Table 5.5-AG (Cumulative Effect on *Water District Service Areas* ~~Theoretical water Supply and Suppliers~~) examines theoretical water supply needs according to major water district. Table 5.5-AF (Cumulative Effect on Theoretical Wastewater Treatment Demand) summarizes theoretical demand for wastewater treatment facilities (as indicated by wastewater generation). *Lastly, Table 5.5-AH (Cumulative Effect on Groundwater Basins) shows development effects on the various groundwater basins underlying Riverside County. To ensure* ~~For ensuring~~ worst-case effects are shown, the calculations assume 100% of the wastewater generated is collected by sanitary sewer systems and processed at wastewater treatment facilities. In reality, a certain amount of the wastewater generated would be disposed of via onsite waste treatment systems (particularly individual septic systems). For water demand, all values are assumed to be for potable water; no use of recycled, reclaimed or graywater, which would reduce demand, is assumed. Also, no SBX-7x7 (Water Conservation Act of 2009) required water conservation reductions were included in any of these calculations, even though in reality reductions of up to 20% by 2020 are to be pursued per this law. These assumptions ensure the scenarios model "worst case" conditions.

As shown in tables below, build out of each of the various General Plan scenarios shown will contribute incrementally to utilization of existing water and sewer infrastructure, as well as increase demand for water from both local and imported sources. In addition to introducing additional demand for water and sewer, future development will alter existing hydrology, increase urban runoff while decreasing groundwater recharge and affect water quality.

Footnotes:

1. Groundwater basins encompassed by the regions listed:
   Western Region (from Orange County to the San Jacinto Mountains):
   Buck Ridge Fault Valley, Cahuilla Valley, Collins Valley, Coastal Plain of Orange County, Elsinore, Hemet Lake Valley

Ocotillo-Clark Valley	San Jacinto	Temecula Valley
Terwilliger Valley	Upper Santa Ana Valley	Vanderventer Flat

Coachella Valley Region (east of the San Jacinto Mountains):

Chocolate Valley	Coachella Valley	East Salton Sea
Orocopia Valley		

Far Eastern Region (east of Coachella Valley to Arizona border at the Colorado River):

Arroyo Seco Valley	Cadiz Valley	Calzona Valley
Chuckwalla Valley	Dale Valley	Hexie Mountain Area
Joshua Tree	Lost Horse Valley	Palo Verde Mesa
Palo Verde Valley	Pinto Valley	Pleasant Valley
Quien Sabe Point Valley	Rice Valley	Vidal Valley
Ward Valley	Warren Valley	

None (areas with no groundwater basin underlying)

2. All areas in acres, reflecting development of land overlying the groundwater basins.
3. CURR GP = General Plan as of end of *2009* ~~2008~~. GPU W/960 = General Plan as amended per GPA No. 960. CULM GP/GPAS = General Plan amended per list of proposed GPAs. See Section 5.5.1 for full descriptions.
4. Change from current General Plan (CURR scenario).
5. Net totals always equal zero since all lands are 100% accounted for by the development categories shown.
6. *See Tables 16.1 through 16.4 in Appendix EIR-11 for more detailed data used.*

Source: Riverside County GIS *(RCIT)*, RCLIS layer (water districts); project application data, 2013 *and 2014*; water factors from EIR No. 441, 2003.

For potable water, Table 5.5-AE indicates existing General Plan build out will nearly double demand by roughly *318,000* ~~236,000~~ acre-feet per year. *(One acre-foot equals roughly 326,000 gallons and is commonly considered enough water to serve a suburban household for a year.)* Meeting this demand will require additional water supplies from a combination of imported (i.e., state), local (groundwater) and recycled/ reclaimed water sources. All of these supply sources are extremely limited in their capacities to provide additional water. Increased reliance on local groundwater sources would further increase the rate of basin drawdown and the cumulative effects, such as poor water quality and harm to biota, that result. Although there is room for increased utilization of recycled and reclaimed water sources, and indeed most water districts are aggressively pursuing improved efficiencies for these sources, such programs remain relatively costly using current technologies.

As a result, even though build out of the General Plan with the project added (GPU/GPA960 scenario) would incrementally *decrease* ~~increase~~ cumulative potable water demand ~~only~~ slightly *(as compared to existing General Plan build out [CURR scenario])*, the project's contribution is still cumulatively considerable on a countywide basis *when compared to baseline environmental conditions (EXIST scenario)*. The cumulative GPAs build out (CULM) scenario, with *a 4%* ~~an 11%~~ increase in demand over the existing General Plan, would *also* have *a* ~~an even greater~~ cumulatively significant impact on water supply. Thus, based on the present level of water planning and supply allocation for the state in general, and the water agencies serving Riverside County in particular, build out of any of the General Plan scenarios would cumulatively result in an "insufficient water supply" within Riverside County.

Table 5.5-AG shows a *theoretical* projection of how *additional development accommodated by the various scenarios would* ~~the~~ increase~~d~~ demand for water supplies within *each of the service areas of* ~~Riverside County might affect~~ the various major (wholesale) water suppliers located in Riverside County. *Continued urbanization and growth within western Riverside County would yield increases of 50-100% in developed uses needing potable water service within the major water districts' service areas (particularly EMWD and WMWD). Similar trends would also occur in the Coachella Valley. Though currently less developed than western county areas, the Coachella Valley increases are even more cumulatively significant due to the extremely limited water supply to the region and its extremely hot and dry desert climate. For both regions, however, impacts to available water supplies will be cumulatively significant for any of the build out scenarios analyzed.*

Of ~~In~~ particular *concern are* the *areas that fall under* ~~subtotal for~~ "Rest (Not in Water Districts)," *which are* ~~indicates that~~ areas not served by existing water agencies. *As such, development in these areas must rely upon self-produced water, typically from on-site (or local area) groundwater pumping* ~~would see large cumulative increases, roughly doubling the amount of groundwater that would be pumped by individual landowners~~, assuming such water is available and of

sufficient quality for residential use. *All three scenarios show a common trend of large losses of vacant open space areas as development spreads further in the interface fringe and wildland areas of Riverside County. Because of the remote nature of such areas and lack of public water services, this type of development pattern has a significant effect on groundwater basins. Notwithstanding recent changes in California water law, the pumping of groundwater on private property is largely unregulated and unconstrained. For this reason, groundwater demand is a classic example of the type of incremental uses that are individually inconsiderable (e.g., groundwater pumped and used by an individual household) but cumulatively significant. As a result of the incremental usage,* where *net* demand exceeds recharge rates, such levels of groundwater drawdown are not sustainable, particularly in dry years or during prolonged drought conditions. *The resultant drawdown causes significant adverse environmental impacts, both to the homeowner, who's well may go dry, and to the natural ecosystem, plants and animals that all rely on local water supplies for their survival.*

In regards to effects on local, groundwater supplies, Table 5.5-AH shows the amount of land within the various regions' basins affected by the various development categories. (Basins are grouped by region because they are too numerous to depict individually; see Appendix EIR-11 for full details and data.) In the urbanizing regions (western Riverside County and the Coachella Valley), the table shows the general trend of lands going from less intense interface/wildland uses vacant/open space uses to more intense urban/suburban uses. The mostly rural areas (far east region and areas not underlain by any groundwater basin) show a similar shift from rural to urban as well. ~~In terms of build out, the with-project (GPU/GPA960) scenario shows changes ranging mostly between 1% and 3%. The most notable exception is the 12% increase in urban/suburban land uses that would occur outside of known groundwater basins; an increase that~~ *Both the with-project (GPU) and CULM build out scenarios show the familiar trend of growth and urbanization pressures causing interface areas and wildlands to convert to more rural, suburban and urban uses. This trend is particularly evident in the Coachella Valley. As a result, both the GPU and CULM scenarios show that development footprints would increase over the watersheds and groundwater basins in the Coachella Valley. Their extent would be slightly less extensive than the current General Plan (CURR scenario) everywhere outside of the Coachella Valley. Nevertheless, for all of the groundwater basins associated with increasing development footprints, the growth associated with any of the General Plan build out scenarios* would be cumulatively considerable if imported water supplies are limited or unavailable in these areas. ~~For the cumulative GPAs (CULM) scenario, build out would yield similar trends, but with greater cumulative contributions. Unmitigated impacts would be cumulatively considerable as well.~~

Lastly, Table 5.5-AF shows that the cumulative effects of increased generation of wastewater (sewage) would have a similar pattern of impact on wastewater treatment plants. Under the existing General Plan (CURR scenario), demand would increase *111%* ~~roughly 60%~~, a cumulatively significant increase. The with-project (GPU/GPA960) scenario would *slightly* incrementally *decrease* ~~increase~~ this demand ~~by roughly 3%~~ and the CULM scenario would increase it by roughly *5%* ~~11%~~. Unlike water supplies, which are extremely limited, there *are* no restraints *(other than economic)* to the ability to increase wastewater treatment capacity. Careful planning and implementation by the responsible agencies would be sufficient to ensure the timely provision of needed wastewater treatment capacity through expansion of existing or construction of new facilities. Thus, the incremental increases associated with the GPU and CULM scenarios would not be cumulatively substantial if managed appropriately.

c. Impacts

Future development will contribute incrementally to cumulative impacts on water resources as the county builds out over time pursuant to the County General Plan (regardless of scenario). Specific impacts of the severities indicated will include the following:

(1) Cumulatively Considerable Impacts

- Future development (pursuant to any of the build out scenarios discussed, including the with-project scenario) will incrementally increase demand for water supplies in areas where such supplies are insufficient or unavailable to serve the project from existing entitlements and resources. This will necessitate new or expanded water supplies (entitlements) in order to adequately serve future development. In some areas, the adequacy of water supplies is already known to be insufficient or supplies are already utilized at their maximum sustainable level. In both cases, water supplies would be insufficient to meet incremental increases in demand using existing technologies.

- Due to the variability and unpredictability of water supplies from year to year, in some cases, the adequacy of future water supplies cannot be ascertained at this time at the programmatic level of this EIR. Thus, in light of future growth, as well as environmental and regulatory constraints, adequate water supplies for all forecast future development cannot be assured. As a result, in areas of Riverside County where sufficient water supply is not available or cannot be assured into the future, cumulative impacts would be significant and unavoidable.

- Unavailability or unpredictability of imported water supplies, overdraft of groundwater basins, increasing demand due to growth in Riverside County, as well as environmental factors, such as climate change effects and drought, all play roles in limiting the availability of water within Riverside County. In some remote locations, particularly in the far eastern desert beyond the Coachella Valley and the region south of the San Jacinto Mountains between Anza and Coachella Valley, lack of groundwater and lack of delivery infrastructure also are limiting factors. For all of these reasons, the cumulative effects on water supply would be significant and unavoidable at this time.

- In attempting to meet the increased demand for water outlined above, future development from any General Plan build out scenario would incrementally increase use of local groundwater supplies, both by water districts and individual landowners through private pumps. This is particularly likely in areas of Riverside County without municipal water service or other access to imported water supplies or where new development would rely solely on groundwater for supply. Increased development will incrementally increase the impermeable surfaces in Riverside County, interfering with groundwater recharge. Where increased groundwater pumping exceeds the rate of basin recharge, it would cumulatively result in the substantial depletion of groundwater in Riverside County.

- Incremental increases in the use of groundwater may also conflict with groundwater management plans, monitoring programs or lead to groundwater extractions that individually or cumulatively exceed the groundwater basins' safe yields or cause a net deficit in the aquifer volume or reduction in the local water table level.

- In the search for new water supplies, groundwater of marginal quality, high in salts or organic compounds, may be extracted and treated to meet drinking water standards and distributed for domestic and municipal uses. This action risks the overuse and overdraft of groundwater in basins with little history of extensive extraction. Increasing demands and costs, as well as unpredictability in the availability of imported water, would make it more attractive for water suppliers to exploit the local groundwater supplies, including at times those of marginal water quality. Where groundwater is extracted at a faster rate than it is replenished, problems associated with overdraft and lowering groundwater tables would occur or continue.

- A number of factors will result in or contribute incrementally to substantially decreasing groundwater supplies: increased demand for water associated with the growth envisioned by the General Plan, supply and cost unpredictability, variability in long-term supply scenarios in non-adjudicated basins, exploitation of new groundwater sources and the continuing pattern of basin overdraft.

- In addition, an assessment of future water supply adequacy beyond the year 2035 (including groundwater) is speculative. Since at present roughly one-third of Riverside County's water demand is met by groundwater, this unpredictability and variability mean that significant cumulative impacts associated with build out over the next 50-plus years cannot be ruled out.

- Future development per build out of any of the General Plan scenarios would incrementally increase water erosion, sedimentation and siltation of surface water. These include short-term construction impacts, as well as long-term operational impacts. Future development will also incrementally damage or change hydrologic baseline conditions throughout Riverside County over time. Compliance with existing laws, General Plan policies and existing EIR No. 441 mitigation measures, would ensure that such impacts are cumulatively less than significant in areas in which development occurs pursuant to a Master Drainage Plan or per a drainage plan required as part of tract or parcel development. However, where such plans do not exist or are not required, for example, for individual homes in wildlands and on expanding urban fringes, new development could contribute incrementally to cumulatively considerable hydrological impacts.

- Increased development resulting from General Plan implementation would also incrementally reduce the distribution and extent of permeable surfaces suitable for recharge. It may also increase runoff and subsequent flow in streams, and increase the amount of non-point source pollutants that enter watercourses and recharge areas. Development activities may also result in the incremental alteration or elimination of features essential to local or regional hydrologic systems, or the interruption of hydrologic processes leading to cumulatively considerable impacts.

- Build out of any of the General Plan scenarios would result in the incremental development of vacant lands within Riverside County. The addition of impervious surfaces from such development would incrementally increase stormwater runoff within the affected watersheds. In some areas, existing drainage facilities may not be adequate to accommodate the increase, leading to cumulatively significant impacts to existing stormwater drainage facilities or triggering the need for new facilities.

- New land uses would incrementally increase the amount of stormwater runoff due to the increase in impermeable surfaces. This would also increase the amount of pollutants conveyed to groundwater basins and surface waters in creeks and rivers. The extensive stormwater management measures required by the County of Riverside would reduce urban runoff impacts from new development. However, where existing storm drainage facilities are inadequate or, in particular, where no regional stormdrain infrastructure exists (e.g., in wildland and fringe areas), incremental increases in runoff would result in cumulatively significant impacts.

(2) Non-Substantial Incremental Impacts

- Future development per build out of any of the General Plan scenarios will incrementally increase water demands, thus increasing reliance on lower-quality water either from the Colorado River or marginal groundwater sources. It would also contribute to increased levels of pollutants in local/regional groundwater reserves and local/regional surface waters. These conditions would contribute incrementally to the deterioration of drinking water quality in Riverside County. However, as all potable

water must meet the state's minimum standards of purity for water quality, adherence to such standards would ensure that cumulative impacts are not significant.

- Future development will incrementally increase Riverside County's population, increasing the amount of wastewater generated, increasing the need for effluent disposal. When discharged into a stream or other surface water, effluents can degrade water quality. Additionally, stormwater runoff from urban areas contains a variety of organic and inorganic substances that would also reduce the quality of groundwater when introduced into their aquifers. Adherence to strict state water quality standards would ensure such impacts are not cumulatively considerable.

- Future development will result in incremental changes to existing hydrology, increased impervious surfaces and increased urban runoff. Such changes would increase the discharge of pollutants into receiving waters, if not properly managed and controlled. Compliance with the state's extensive water quality regulations, including MS4 permits (for municipal separate storm sewer systems) and the NPDES program of the federal Clean Water Act, would ensure that no significant violations of water quality standards or waste discharge requirements occur individually or cumulatively.

- Future development pursuant to any of the General Plan build out scenarios will incrementally increase the amount of wastewater (sewage) generated in Riverside County. All such wastewater must be disposed of pursuant to a variety of state and federal water quality laws (see list below). Accordingly, compliance with extensive regulations would ensure that future development does not individually or cumulatively exceed any wastewater treatment requirements. Similar compliance requirements that strictly regulate the construction and maintenance of septic tanks will ensure that incremental increases in use of septic systems do not result in cumulative exceedance of wastewater treatment requirements.

- Future development will incrementally increase wastewater generation, increasing the need for its treatment and potentially exceeding the capacities of existing treatment facilities, necessitating the construction of additional facilities. In addition, where sanitary sewer connection and treatment are not available, septic systems would be necessary. The proliferation of septic systems in rural communities may potentially contaminate groundwater with nitrates, ammonia, salts, metals, organic solvents, grease and oil, and other substances, impairing the beneficial uses of local water supplies. However, compliance with existing laws, regulatory programs, ordinances, General Plan policies and existing mitigation measures from EIR No. 441 would be sufficient to ensure that cumulative impacts associated with wastewater treatment capacities are less than significant.

- Future development would incrementally increase demand for water supply, wastewater treatment and infrastructure to supply these services. These increases would contribute incrementally to the need for new or expanded water and wastewater treatment facilities. Since future development would be implemented on a case-by-case basis across many individual sites spread across Riverside County over roughly 50 years, however, it would not result in significant impacts tied to specific, inalterable areas. Rather, the future locations of such facilities can be established (located) so as to minimize potential environmental effects. Thus, cumulative impacts due to the need for new or expanded water and wastewater facilities would not be significant.

- Future growth per any of the General Plan build out scenarios would result in the development of vacant lands and infill of existing land uses within Riverside County. This would introduce additional impervious surfaces, incrementally increasing stormwater runoff throughout Riverside County. Existing drainage facilities may not be adequate to accommodate future increases in stormwater runoff. As a result, additional storm drain capacity and facilities will be necessary. It is feasible, however, for such

future facilities to be planned, sited and constructed in a manner that minimizes potential environmental effects. Thus, these impacts would not be cumulatively significant.

d. Mitigation

As described in detail in Section 4.19.5, a variety of measures would be implemented to avoid, reduce and minimize adverse cumulative water resource impacts. These include the following:

(1) Regulatory Compliance

Key Regulations and Program: See Section 4.19.6 for details on each regulation.

- Federal Water Pollution Control Act of 1972 (aka the Clean Water Act)
- Federal Safe Drinking Water Act
- CWA Section 402 - National Pollutant Discharge Elimination System (NPDES)
- California Porter-Cologne Water Quality Control Act of 1970
- California Safe Drinking Water Act
- CCR Title 22 - Recycled Water
- Water Conservation Act - SBX 7-7
- Senate Bill 610 – re Water Supply Assessment Requirements
- Senate Bill 221 – re Water Supplies for Subdivisions
- Ordinance No. 427 - Regulating the Land Application of Manure
- Ordinance No. 457 - Building Codes and Fees
- Ordinance No. 458 - Regulating Flood Hazard Areas and Implementing the National Flood Insurance Program
- Ordinance No. 461 - Road Improvement Standards
- Ordinance No. 592 - Regulating Sewer Use, Sewer Construction and Industrial Wastewater Discharges in County Service Areas
- Ordinance No. 617 - Hazardous Substances and Underground Storage Tanks
- Ordinance No. 629 - Prohibiting Bathing, Swimming, Boating or Entering Irrigation Canals, Ditches or Drains in Unincorporated Areas of Palo Verde Valley
- Ordinance No. 650 - Sewer Discharge in Unincorporated Territory

- Ordinance No. 659 - Development Mitigation Fee for Residential Development (DIF)
- Ordinance No. 682 - Construction, Reconstruction, Abandonment and Destruction of Wells
- Ordinance No. 754 - Stormwater/Urban Runoff Management and Discharge Controls
- Ordinance No. 830 - Regulating the Land Application of Class A Sewage Sludge for Agricultural Activities
- Ordinance No. 843 - Regulating the Discharge of Wastes into the Public Sewer System for the Highgrove Community
- Ordinance No. 856 - Establishing a Septic Tank Prohibition for Specified Areas of Quail Valley and Requiring the Connection of Existing Septic Systems to Sewer
- Ordinance No. 859 - Water-Efficient Landscape Requirements
- Ordinance No. 871 - Prohibiting the Installation of Specified Septic Tank Systems in Cherry Valley

Program Funding: The County of Riverside and cities collect taxes, fees and other revenue that is used to fund MS4 permit compliance program activities, as well as other water quality protection programs. These include assessment areas, such as the Whitewater River Watershed Benefit Assessment Area, which were established as funding sources for MS4 permit (and individual NPDES) compliance. For Whitewater, assessments are calculated on the basis of proportional stormwater runoff and are enrolled on the property tax bills generated by the County Tax Assessor's office. Some County Service Areas (CSAs), for example CSA 152, also collect funds similarly or use general ("ad valorem") tax revenues to finance stormwater management programs.

Key General Plan Policies: Although the General Plan does not include a Public Services or Utilities Element, it does include a number of policies that address water resources and related facilities. These policies help ensure that cumulative environmental effects are avoided, reduced or minimized through their application on a case-by-case basis. The County of Riverside has existing programs in place that ensure applicable policies are imposed once a development proposal triggers a specific policy or policies. The need for specific policies is determined through subsequent site-specific CEQA analysis performed at the time of implementing project review. These measures are implemented, enforced and verified through their inclusion into project conditions of approval. See Section 4.19.3.c for full text of each policy.

- Land Use Element Policies: LU 5.3, 9.1, 9.2-9.4, 21.2, 22.2, 28.3, 29.7, 30.7, 31.4 and 32.6
- Open Space Element Policies: OS 1.1, 1.3, 1.4, 2.1-2.5, 3.1-3.7, 4.1-4.6, 4.8, 6.1, 6.3 and 18.1-18.6

(2) CEQA Mitigation

Existing Mitigation Measures: These specific mitigation measures from EIR No. 441 address the various water resource and related impacts directly to reduce, avoid or minimize the applicable impacts and will also apply to future development:

- **Existing MM 4.9.1C:** Riverside County shall not necessarily require all land uses to withstand flooding. These may include land uses such as agricultural, golf courses, and trails. For these land uses, flows shall not be obstructed, and upstream and downstream properties shall not be adversely affected by increased

velocities, erosion backwater effects, concentration of flows, and adverse impacts to water quality from point and nonpoint sources of pollution.

- **Existing MM 4.9.1.D:** Riverside County shall require the 10-year flood flows to be contained within the top of curbs and the 100-year flood flows within the street rights-of-way.

- **Existing MM 4.9.2C:** Riverside County shall require that for agricultural, recreation or other low-density uses, flows are not obstructed and that upstream and downstream properties are not adversely affected by increased velocities, erosion backwater effects or concentration of flows.

- **Existing MM 4.10.9A:** Riverside County, where required, and in accordance with issuance of a National Pollutant Discharge Elimination System (NPDES) permit, shall require the construction and/or grading contractor for individual developments to establish and implement specific Best Management Practices (BMPs) at time of project implementation.

- **Existing MM 4.10.9B:** Prior to any development within the County [of Riverside], a grading plan shall be submitted to the Riverside County Building and Safety Department and/or Riverside County Geologist for review and approval. As required by the County [of Riverside], the grading plan shall include erosion and sediment control plans. Measures included in individual erosion control plans may include, but shall not be limited to, the following:

  a. Grading and development plans shall be designed in a manner which minimizes the amount of terrain modification.

  b. Surface water shall be controlled and diverted around potential landslide areas to prevent erosion and saturation of slopes.

  c. Structures shall not be sited on or below identified landslides unless slides are stabilized.

  d. The extent and duration of ground disturbing activities during and immediately following periods of rain shall be limited, to avoid the potential for erosion which may be accelerated by rainfall on exposed soils.

  e. To the extent possible, the amount of cut and fill shall be balanced.

  f. The amount of water entering and exiting a graded site shall be limited through placement of interceptor trenches or other erosion control devices.

  g. Erosion and sediment control plans shall be submitted to the County [of Riverside] for review and approval prior to the issuance of grading permits.

- **Existing MM 4.10.9C:** Where required, drainage design measures shall be incorporated into the final design of individual projects on-site. These measures shall include, but will not be limited to:

  a. Runoff entering developing areas shall be collected into surface and subsurface drains for removal to nearby drainages.

  b. Runoff generated above steep slopes or poorly vegetated areas shall be captured and conveyed to nearby drainages.

c. Runoff generated on paved or covered areas shall be conveyed via swales and drains to natural drainage courses.

d. Disturbed areas identified as highly erosive shall be (re)vegetated.

e. Irrigation systems shall be designed, installed and maintained in a manner which minimizes runoff.

f. The landscape scheme for projects within the project site shall utilize drought-tolerant plants.

g. Erosion control devices such as rip-rap, gabions, small check dams, etc., may be utilized in gullies and active stream channels to reduce erosion.

- **Existing MM 4.15.4A:** Conventional septic tanks/subsurface disposal systems shall be prohibited within any designated Zone A of an EPA wellhead protection area. Where a difference between Riverside County and EPA septic tank setback distance requirements exists, the EPA standard shall apply.

- **Existing MM 4.17.1C:** Development within unincorporated areas of the County [of Riverside] shall not use water of any source of quality suitable for potable domestic use for non-potable uses, including cemeteries, golf courses, parks, highway landscaped areas, industrial and irrigation uses, or other non-domestic use if suitable recycled water is available as provided in Sections 13550-13566 of the [California] Water Code and/or Sections 65591-65600 and 65601-65607 of the Public Resource Code. Prior to the issuance of any land use permit, the County [of Riverside] shall determine to what extent and in which manner the use of recycled water is required for individual water projects. Future development shall be designed, constructed and maintained in accordance with the recycled water measures mandated by the County [of Riverside].

- **Existing MM 4.17.1D:** Riverside County shall enforce compliance with federal, state and local standards for water conservation within residential, commercial or industrial projects. Prior to approval of any development within the County [of Riverside], the applicant shall submit evidence to Riverside County that all applicable water conservation measures have been met.

- **Existing MM 4.17.1E:** For any development within the [DWR-designated] Palo Verde Planning Area supplied with water from the Colorado River, the project applicant shall enter into a contract with the City of Needles [the LCWSP water contractor], pursuant to the Lower Colorado Water Supply Project program. Evidence of such a contractual agreement shall be submitted to the County [of Riverside] prior to the approval of any development entitlement for the project.

- **Existing MM 4.17.2A:** In areas where it is not practical to conserve soils suitable for recharge (as determined by the Riverside County Flood Control and Water Conservation District), water harvesting and recharge facilities shall be built within the same groundwater basin in which the recharge area is lost. The construction of "replacement" recharge areas shall equal the amount of recharge area lost and/or shall incorporate equipment or facilities capable of replacing (at an equal volume) the amount of groundwater recharge capacity lost as a result of development. The identification, designation, location or installation of "replacement" groundwater recharge capacity shall be reviewed and approved by the Riverside County Flood Control and Water Conservation District prior to the issuance of grading permits.

- **Existing MM 4.17.3A:** New development that includes more than one acre of impervious surface area (including roofs, parking areas, streets, sidewalk, etc.) shall incorporate features to facilitate the onsite

infiltration of precipitation and/or runoff into groundwater basins. Such features shall include (but not be limited to): natural drainage systems (where economically feasible), detention basins incorporated into project landscaping; and the installation of porous areas within parking areas. Where natural drainage systems are utilized for groundwater recharge, they shall be managed using natural approaches (as modified to safeguard public health and safety). Groundwater recharge features shall be included on development plans and shall be reviewed by the Riverside County Building and Safety Department and/or Riverside County Flood Control and Water Conservation District prior to the issuance of grading permits.

- **Existing MM 4.17.4A** Where development may interfere with, disrupt, or otherwise affect surface or subsurface hydrologic baseline conditions (as determined by the Riverside County Flood Control and Water Conservation District, the United States Army Corps of Engineers, the California Department of Fish and Game [now California Department of Fish and Wildlife], and/or the Regional Water Quality Control Board), preparation of a project specific hydrologic study shall be required. The hydrologic study shall include (but shall not be limited to): an inventory of surface and subsurface hydrologic conditions existing at the time of the study; an analysis of how the proposed development would affect these hydrologic baseline conditions; and specific measures to limit or eliminate the interference or disruption of the on-site hydrologic process. The hydrologic study shall evaluate the feasibility of incorporating bioengineering measures into any project that may alter the hydrologic process. Where required by the County [of Riverside], the hydrologic study shall include analysis of, at an equal level of detail, potential impacts to tributary or downstream areas. The hydrologic study shall be submitted to the County [of Riverside] or responsible entity for review and shall be approved prior to the issuance of any entitlement that would result in the physical modification of the project site.

- **Existing MM 4.17.4B:** The project applicant shall submit to the County [of Riverside] for review and approval, evidence that the specific measures to limit or eliminate the disruption or interference to the hydrologic process resulting from the entire development process, will be implemented as set forth in the hydrologic study. Such evidence may take the form of (but shall not be limited to): a development agreement; land banking; the provision of adequate funds to guarantee the construction, maintenance or restoration of hydrologic features; or any other mechanism that will achieve said goals. Said evidence shall be submitted and approved prior to the issuance of any entitlement that would result in the physical modification of the project site.

- **Existing MM 4.17.4C:** Where determined feasible by the County [of Riverside] or responsible entity, bioengineering measures shall be incorporated into any project that may alter the hydrologic process.

- **Existing MM 4.17.5A:** The development of septic systems shall be in accordance with applicable standards established by Riverside County and other responsible authorities.

- **Existing MM 4.17.5B:** Point source pollution reduction programs shall fully adhere to applicable standards required by federal, state and local agencies. Prior to the approval of individual projects, Riverside County shall verify that the provisions of applicable point source pollution programs have been satisfied.

- **Existing MM 4.17.5C:** Where development may contribute to a worsening of local or regional ground or surface water quality (as determined by the Riverside County Department of Environmental Health and/or RWQCB), a water quality analysis shall be prepared. The water quality analysis shall include (but shall not be limited to): an analysis of existing surface and subsurface water quality; an assessment of how the proposed development would affect existing water quality; an assessment of how the proposed

development would affect beneficial uses of the water; and specific measures to limit or eliminate potential water quality impacts and/or impacts to beneficial uses of ground/surface water. Where determined necessary by the County [of Riverside] or other responsible entity, the water quality analysis shall include, at an equal level of detail, potential impacts to tributary or downstream areas. The water quality analysis shall be submitted to the County [of Riverside] and the RWCQB for review and shall be approved prior to the issuance of any entitlement that would result in the physical modification of the project site.

- **Existing MM 4.17.5D:** The project applicant shall submit to the County [of Riverside] and the RWQCB, for review and approval, evidence that the specific measures to limit or eliminate potential water quality impacts resulting from the entire development process, will be implemented as set forth in the water quality analysis. Said evidence shall be submitted and approved prior to the issuance of any entitlement that would result in the physical modification of the project site.

- **Existing MM 4.17.5E:** For each new development project, the following principles and policies shall be considered and implemented:

  a. Avoid or limit disturbance to natural water bodies and drainage systems (including ephemeral drainage systems) when feasible. Provide adequate buffers of native vegetation along drainage systems to lessen erosion and protect water quality.

  b. Appropriate best management practices (BMPs) must be implemented to lessen impacts to Waters of the United States and/or Waters of the State of California resulting from development. Drainages should be left in a natural condition or modified in a way that preserves all existing water quality standards where feasible. Any discharges of sediment or other wastes, including wastewater, to Waters of the United States or Waters of the State must be avoided to the maximum extent practicable. All such discharges will require an NPDES permit issued by the Regional Water Quality Control Board (RWQCB).

  c. Small drainages shall be preserved and incorporated into new development, along with adequate buffer zones of native vegetation, to the maximum extent practicable.

  d. Any impacts to Waters of the United States require a Section 401 Water Quality Standards Certification from the RWQCB. Impacts to these waters shall be avoided to the maximum extent practicable. Where avoidance is not practicable, impacts to these waters shall be minimized to the maximum extent practicable. Mitigation of unavoidable impacts must, at a minimum, replace the full function and value of the affected water body. Impacts to Waters of the United States also require a Clean Water Act Section 404 Permit from the United States Army Corps of Engineers and a Streambed Alteration Agreement from the California Department of Fish and Game [now California Department of Fish and Wildlife].

  e. The County [of Riverside] shall encourage the use of pervious materials in development to retain absorption and allow more percolation of stormwater into the ground. The use of pervious materials, such as grass, permeable/porous pavement, etc., for runoff channels and parking areas shall also be encouraged. Lining runoff channels with impermeable surfaces, such as concrete or grouted riprap, will be discouraged.

  f. The County [of Riverside] shall encourage construction of detention basins or holding ponds and/or constructed wetlands within a project site to capture and treat dry weather urban runoff and the first

flush of rainfall runoff. These basins should be designed to detain runoff for a minimum time, such as 24 hours, to allow particles and associated pollutants to settle and to provide for natural treatment.

g. The County [of Riverside] shall encourage development to retain areas of open space as natural or landscaped to aid in the recharge and retention of runoff. Native plant materials shall be used in replanting and hydroseeding operations, where feasible.

h. The County [of Riverside] shall require that environmental documents for proposed projects in areas tributary to Canyon Lake Reservoir, Lake Elsinore, sections of the Santa Ana River, Fulmar Lake, and Mill Creek (as a result of the proposed 2002 303 (d) listing of these waterbodies) include discharge prohibitions, revisions to discharge permits, or management plans to address water quality impacts in accordance with the controls that may be applied pursuant to state and federal regulation. Environmental documents shall acknowledge that additional requirements may be imposed in the future for projects in areas tributary to the water bodies listed above.

i. The County [of Riverside] shall ensure that in new development, post-development stormwater runoff flow rates do not differ from the pre-development stormwater runoff flow rates.

j. All construction projects should be designed and implemented to protect, and if at all possible, to improve the quality of the underlying groundwater.

k. The County [of Riverside] shall encourage the enhancement of groundwater recharge wherever possible. Measures such as keeping stream/river channels and floodplains in natural conditions or with pervious surfaces, as well as keeping areas of high recharge as open space will be considered.

l. The County [of Riverside] shall prohibit the discharge of waste material resulting from any type of construction into any drainage areas, channels, streambeds, streams, lakes, wetlands or rivers. Spoil sites shall be prohibited within any streams or areas where spoil material could be washed into a water body.

m. The County [of Riverside] shall require that appropriate BMPs be developed and implemented during construction efforts to control the discharge of pollutants, prevent sewage spills, and to avoid discharge of sediments into the streets, stormwater conveyance channels or waterways.

New Mitigation Measures: EIR No. 521 also includes the following measure to ensure that cumulative impacts associated with wastewater treatment are reduced to less than significant.

- **New MM 4.19.E-N1:** Conventional septic tanks/subsurface disposal systems shall be prohibited within any designated Zone A of an EPA wellhead protection area. Where a difference between Riverside County and EPA septic tank setback distance requirements exists, the more restrictive standard shall apply.

e. Significance

Implementation of all of the above regulations, General Plan policies and mitigation measures, would help reduce, avoid or minimize various cumulative impacts to water resources, including supplies, infrastructure, water quality, hydrology and storm drainage. However, while many of these impacts will be *individually* less than significant, for some water impacts incremental impacts will be *cumulatively* substantial, even with the implementation of all feasible mitigation. Specifically, impacts that would be cumulatively significant under any of the build out

scenarios examined herein, including the project (GPA No. 960), include: incremental increases in the demand for water supply; incremental increases in groundwater usage and its recharge; incremental changes to existing drainage patterns, erosion, sedimentation and siltation; and, incremental increases in runoff due to development of additional impervious surfaces. For these areas, cumulative impacts would be significant and unavoidable.

D. Cumulative Analysis - Conclusions

In total, the above analyses indicate that the project, GPA No. 960, would have a number of cumulatively significant incremental impacts as a result of future development implementing the updated Riverside County General Plan. These cumulative impacts are summarized in Table 5.5-AI (Project Cumulative Impacts Summary), below. In many cases, the reduced development footprint, updated circulation network and enhanced environmental policies put forth by GPA No. 960 will result in *reduced* cumulative impacts compared to those originally forecast for the 2003 RCIP General Plan (as per its accompanying EIR No. 441).

However, given that GPA No. 960's changes will affect numerous, perhaps even thousands, of future individual General Plan-implementing projects over time, when compared against the environmental baseline (existing conditions), the project will still result in cumulatively significant environmental impacts. As outlined above in the various subsections of this analysis, in some cases the project's cumulative impacts would also be less than those forecast for the cumulative General Plan (CULM) scenario, that is the General Plan as it would be should all the GPAs listed in Table 5.5-A were adopted.

Table 5.5-AI: Project Cumulative Impacts Summary

Impact #	Cumulative Impact Title / Description [1]	No Impact	Incremental, Non-Substantial	Cumulatively Substantial/ Significant
4.2 – Land Use				
4.2.A	Physically divide an established community.		•	
4.2.B	Conflict with land use policies to avoid or mitigate an environmental effect.		•	
4.2.C	Conflict with any habitat conservation or natural community conservation plan.		•	
4.3 – Population and Housing				
4.3.A	Induce direct or indirect population growth.			•
4.3.B	Displace residential units.		•	
4.3.C	Displace people.		•	
4.4 – Aesthetic and Visual Resources				
4.4.A	Adversely affect scenic vistas.			•
4.4.B	Adversely affect scenic resources within State Scenic Highways.			•
4.4.C	Adversely affect existing visual character.		•	
4.4.D	Cause adverse light and glare effects.			•
4.4.E	Interfere with nighttime use of the Palomar Astronomical Observatory.		•	
4.5 – Agricultural and Forestry Resources				
4.5.A	Cause the conversion of designated Farmlands.			•
4.5.B	Encroach on or conflict with existing agricultural uses.			•
4.5.C	Adversely affect forest lands and forestry uses.		•	
4.6 – Air Quality				
4.6.A	Conflict with air quality plans.			•
4.6.B (1)	Cause significant construction (short-term) air emissions.			•

Impact #	Cumulative Impact Title / Description [1]	No Impact	Incremental, Non-Substantial	Cumulatively Substantial/ Significant
4.6.B (2)	Cause significant operational (long-term) air emissions.			•
4.6.C	Cause cumulatively significant project air quality impacts.			•
4.6.D	Expose sensitive receptors to air pollutants.			•
4.6.E	Expose substantial numbers of people to objectionable odors.		•	
4.7 – Greenhouse Gases				
4.7.A	Generate substantial greenhouse gas emissions.		•	•
4.7.B	Conflict with greenhouse gas reduction plans, policies or regulations.		•	•
4.8 – Biological Resources				
4.8.A	Adversely affect riparian and other sensitive habitats.		•	
4.8.B	Cause direct and indirect impacts to protected species or their habitats.		•	
4.8.C	Adversely affect wetlands.		•	
4.8.D	Impede species movement, migration, wildlife corridors or use of wildlife nursery sites.		•	
4.8.E	Conflict with adopted habitat conservation plans.		•	
4.8.F	Conflict with local biological resource protection policies or ordinances.		•	
4.9 – Cultural and Paleontological Resources				
4.9.A	Adversely change the significance of historical resources.		•	
4.9.B	Cause the destruction of known archeological resources.			•
4.9.C	Cause the destruction of unique paleontological resources or sites.			•
4.9.D	Result in the disturbance of human remains.		•	
4.10 – Energy Resources				
4.10.A	Increase demand for electricity.			•
4.10.B	Increase demand for natural gas.			•
4.10.C	Cause the inefficient use of energy.		•	
4.11 – Flood and Dam Inundation Hazards				
4.11.A	Result in housing within flood hazard areas.		•	
4.11.B	Cause impediment of flows.		•	
4.11.C	Expose people or structures to flooding hazards, including flooding due to dam or levee failure.		•	
4.11.D	Cause the adverse alteration of drainage patterns or substantially increase surface runoff.		•	
4.11.E	Cause inundation risks due to seiche, tsunami or mudflow.		•	
4.12 – Geology and Soils				
4.12.A	Expose people or structures to substantial adverse effects due to rupture of a known earthquake fault.		•	
4.12.B	Expose people or structures to substantial strong seismic groundshaking.			•
4.12.C	Expose people or structures to substantial adverse effects due to seismic-related ground failure, including liquefaction.		•	
4.12.D	Expose people or structures to substantial adverse effects due to landslide.			•
4.12.E	Result in substantial soil erosion or topsoil loss.		•	
4.12.F	Result in development on unstable geological units or soils.		•	
4.12.G	Result in development on expansive soils.		•	
4.12.H	Result in development on soils incapable of supporting septic tanks or alternative wastewater disposal systems.		•	
4.13 – Hazardous Materials and Safety				
4.13.A	Create a significant hazard through the routine transport, use or disposal of hazardous materials.		•	
4.13.B	Cause a significant hazard through the accidental release of hazardous materials.		•	

Impact #	Cumulative Impact Title / Description [1]	No Impact	Incremental, Non-Substantial	Cumulatively Substantial/ Significant
4.13.C	Result in hazardous emissions or related hazards within ¼-mile of a school.		•	
4.13.D	Result in a significant hazard due to development on a Cortese List hazardous materials site.		•	
4.13.E	Result in a safety hazard for people within a two-mile radius of a public or public use airport.		•	
4.13.F	Result in a safety hazard in the vicinity of a private airstrip or heliport.		•	
4.13.G	Impair or interfere with adopted emergency response or evacuation plans.		•	
4.13.H	Expose people or structures to significant risk due to wildland fires.			•
4.14 – Mineral Resources				
4.14.A	Result in the loss of availability of delineated locally important minerals.	•		
4.14.B	Result in the loss of availability of known mineral resources.		•	
4.15 – Noise				
4.15.A	Generate noise or cause noise exposure in excess of standards.			•
4.15.B	Generate or cause exposure to excessive groundborne vibration.		•	
4.15.C	Result in a substantial permanent increase in ambient noise levels.			•
4.15.D	Result in a substantial temporary or periodic increase in ambient noise.			•
4.15.E	Expose people to excessive airport-related noise levels.		•	
4.16 – Parks and Recreation				
4.16.A	Increase the use of existing parks or recreational facilities resulting in their substantial physical deterioration.			•
4.16.B	Trigger growth effects resulting in the need for additional parks or recreational facilities.		•	
4.16.C	Result in significant adverse effects due to the need for additional parks or recreational facilities.		•	
4.17 – Public Facilities				
4.17.A	Cause adverse environmental effects due to the need for fire protection services.			•
4.17.B	Cause adverse environmental effects due to the need for law enforcement services.			•
4.17.C(1)	Adversely affect or exceed the permitted capacity of a landfill.			•
4.17.C(2)	Cause inconsistencies with applicable statutes and regulations related to solid waste, including the Riverside County Integrated Waste Management Plan.		•	
4.17.D	Cause adverse environmental effects due to the need for schools.			•
4.17.E	Cause adverse environmental effects due to the need for library services.			•
4.17.F	Cause adverse environmental effects due to the need for medical facilities.			•
4.18 – Transportation and Traffic				
4.18.A	Conflict with circulation system effectiveness regulations for any mode of transportation, including vehicular, mass transit and non-motorized travel.			•
4.18.B	Conflict with a congestion management program, including level of service (LOS) standards and travel demand measures, or other standards, established by the county congestion management agency for designated roads.			•
4.18.C	Cause substantial safety risks as a result of a change in air traffic patterns.		•	
4.18.D	Cause substantial alterations in waterborne, rail or air traffic.		•	
4.18.E	Substantially increase road hazards due to design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment).		•	
4.18.F	Cause an adverse effect on or need for new or altered road maintenance.		•	
4.18.G	Cause an adverse effect on circulation during construction.		•	
4.18.H	Result in inadequate emergency access or access to nearby uses.		•	
4.18.I	Conflict with policies for public transit or non-motorized travel (bikeways, pedestrian facilities, etc.), or substantially decrease the performance or safety of such facilities.		•	

Impact #	Cumulative Impact Title / Description [1]	No Impact	Incremental, Non-Substantial	Cumulatively Substantial/ Significant
4.19 – Water Resources				
4.19.A	Result in insufficient water supply.			•
4.19.B	Substantially deplete groundwater supplies or substantially interfere with groundwater recharge.			•
4.19.C	Substantially degrade water quality.		•	
4.19.D	Violate water quality standards or waste discharge requirements.		•	
4.19.E	Exceed wastewater treatment requirements.		•	
4.19.F	Exceed wastewater treatment capacity.		•	
4.19.G	Result in significant adverse effects due to the construction of new or expanded water or wastewater facilities.		•	
4.19.H	Substantially alter existing drainage patterns resulting in substantial erosion or siltation.			•
4.19.I	Cause runoff exceeding stormwater drainage system capacities or cause substantial water pollution.			•
4.19.J	Cause significant adverse effects due to the need for new or expanded stormwater drainage facilities.			•
5.2 – Significant Irreversible Changes				
5.2.A	Result in a large commitment of non-renewable resources that make later removal or non-use unlikely.			•
5.2.B	Result in the unjustified commitment of irretrievable resources.		•	
5.2.C	Result in primary or secondary impacts that generally commit future generations to similar uses.			•
5.2.D	Result in an environmental accident that could cause irreversible damage.		•	
5.4 – Significant Growth-Inducing Effects				
5.4.A	Foster direct or indirect economic growth.			•
5.4.B	Foster direct or indirect population growth.			•
5.4.C	Result in construction of additional housing.			•
5.4.D	Remove obstacles to population growth.			•
5.4.E	Facilitate other activities leading to significant environmental effects; e.g., encroach into isolated or remote areas.			•
5.4.F	Result in population increase that may strain community services or facilities.			•

Footnotes:

1. Impacts are based on a comparison of the cumulative effects of build out of the General Plan as amended pursuant to the project, GPA No. 960, compared to environmental baseline. Unless noted otherwise in the text, the environmental baseline is assumed to be the same as or substantially similar to that described for the proposed project in Sections 4.0 through 5.0 of the EIR.

Source: Riverside County Planning Dept., new analysis and results from EIR Sections 4.2 - 4.19 and 5.1-5.5, 2012.

In summary, the analysis herein finds that for the project impacts marked as "Cumulatively Substantial/ Significant" in the table above, the incremental impacts from the project, GPA No. 960, when added to other closely related past, present and reasonably foreseeable or probable future developments which would occur in implementing and building out the Riverside County General Plan, will be cumulatively considerable and unavoidable.

Section 5.6 Consistency with Regional Plans

A. Introduction

Section 15125(d) of the State CEQA Guidelines requires discussion of any inconsistencies between a regionally significant project and regional plans. Within the greater metropolitan region of Southern California, regional

planning is carried out principally by the Southern California Association of Governments (SCAG). SCAG is the state-recognized "Municipal Planning Organization" (MPO) that covers Riverside County and five other counties in Southern California (Los Angeles, Orange, Ventura, San Bernardino and Imperial). The following discussion outlines quantitatively and qualitatively how the General Plan change proposed by the project, General Plan Amendment No. 960 (GPA No. 960), would affect consistency with SCAG's regional plans.

In addition to the SCAG Regional Comprehensive Plan (SCAG Regional Plan) and Compass Blueprint discussed below, the State CEQA Guidelines notes a number of other types of regional plans must also be discussed. For this EIR, these include applicable air quality attainment plans, water quality control plans and others. As noted below, the following regional documents are discussed in the EIR section indicated. Where a document is discussed or analyzed in relation to a specific impact, this is also noted. In accordance with the directives of Section 15126(d), the following regional plans are discussed in this EIR in the following locations:

- **Section 4.3 (Population and Housing):** Regional housing needs allocations.
- **Section 4.6 (Air Quality):** Applicable air quality attainment plans and State Implementation Plans, in particular the discussion for Impact 4.6.A in Section 4.6.6.
- **Section 4.7 (Greenhouse Gases):** Plans for the reduction of greenhouse gas emissions, in particular the discussion for Impact 4.7.B in Section 4.7.6.
- **Section 4.8 (Biological Resources):** Habitat conservation plans and natural community conservation plans, in particular the discussion for Impact 4.8.E in Section 4.8.6.
- **Section 4.17 (Public Facilities):** Area-wide waste treatment plans (see specifically, Section 4.17.4, Solid Waste Management) in particular the discussion for Impact 4.17.C-2 in Section 4.17.4 E.
- **Section 4.18 (Transportation and Traffic):** Regional transportation planning is addressed in Section 4.18.5.
- **Section 4.19 (Water Resources):** Water quality control plans, in particular the discussion for Impact 4.19.D in Section 4.19.8.

B. Regional and Countywide Projections

The most important consistency question at the General Plan level is whether or not the projected demographics of the county (e.g., population, housing and employment figures) are consistent with those used by SCAG. Consistency (or inconsistency) at this fundamental level dictates how the General Plan and the county's long-range planning efforts will dovetail (or clash) with a host of regional SCAG plans, as well as with those of surrounding cities and counties.

When examining regional demographic consistency, two main projections of population, housing and employment are involved: The first is SCAG's 2008 Regional Transportation Plan (RTP-08) that formulates projections up to year 2035. On Riverside County's side is the 2010 Riverside County Projection (RCP-10), which involves data developed by Riverside County Center for Demographics and Research (RCCDR) and approved by the Board of Supervisors. It also projects socioeconomic data for Riverside County's various city and county boundaries to the year 2035.

In addition to Riverside County's primary socioeconomic projections (RCP-10), a second set of projects were developed for the General Plan predicting how Riverside County would look at "full build out" of the county. For this scenario, "full build out" is defined as the point at which all developable land within unincorporated Riverside County has been built upon and all attendant infrastructure, parks, roads, trails, conservation lands, etc., assembled as planned. The year 2060 is the hypothetical end point set for this analysis, hypothetical because the myriad of forces involved in the growth and evolution of human habitation over time mean that a truly "built out" county is exceedingly rare – particularly for one as large as Riverside County (approximately the size of New Jersey). The General Plan's "build out scenario" was developed by the RCCDR and Riverside County Planning Department using the land uses mapped in the existing (*2009* ~~2008~~) General Plan, as reflected by the county's "Riverside County Informational System" (RCLIS) GIS system. The General Plan also includes a variety of policies, policy areas, overlays and other factors affecting the development capacity of Riverside County. Appendix E-1 of the General Plan addresses the methods and assumptions used in developing the build out scenario.

As part of GPA No. 960, a second General Plan build out scenario was created to reflect how Riverside County would look if it developed according to the updated General Plan, that is, including the proposed changes of GPA No. 960. This second set of build out projections represents the "with-project" scenario, while the existing General Plan build out projections represent the "status quo" scenario. For certain demographically driven environmental effects (such as future traffic volumes and numbers of elementary school student, for example), comparisons between these two build out scenarios allows for a clear depiction of how the proposed project would affect the future of Riverside County. This scenario is denoted as the "GPU/GPA960" scenario in Section 5.5 (Cumulative Impacts) and also forms the "No Project/Status Quo" Alternative that was analyzed in Section 6.4.B (Alternatives Analysis).

Lastly, because the General Plan build out scenario projects all the way out to the year 2060, it was necessary for the RCCDR to also create an additional set of projections that took the General Plan (i.e., growth within the county) out just to the year 2035, in order to allow comparison of Riverside County's projections with those of SCAG in the aforementioned RTP-08.

Table 5.6-A, below, encompasses all of these scenarios and shows both the current and proposed updated General Plan build out (2060) scenarios as well as SCAG's RTP-08 projections for Riverside County. By comparing the land use capacity projected for the amended General Plan to SCAG's regional projections, the project can be evaluated on its regional consistency and whether or not the amended General Plan would adequately provide for Riverside County's envisioned future. In reviewing this table, it should be noted that the General Plan build out scenarios represent Riverside County's projected "capacity" for various types of land development – not the literal amount of development expected to occur in the county. It must be remembered that in most cases, such as on private property, for example, the General Plan can only plan and provide for orderly growth within Riverside County – it cannot cause this growth to occur. The overall growth occurring in Riverside County is driven by a combination of many competing factors, including land availability, environmental opportunities and constraints, demographic pressures and a host of economic forces.

Table 5.6-A: Comparison of Various Regional and County Projections

STATISTICS[1]		Year 2035 Projections			Build Out (2060) Projections	
		Riverside County RCP 2010[2]	SCAG RTP 2008[3]	Updated Gen. Plan Capacity[4,5,7]	Current Gen. Plan Capacity[7]	Updated Gen. Plan Capacity[4,5,7]
Population	**Total**	**3,396,300**	**3,596,700**	**n/a**	**n/a**	**n/a**
Unincorporated[6]		909,100	1,243,600	969,100	1,727,400	1,702,700
Incorporated		2,487,200	2,353,000	n/a	n/a	n/a
Residences	**Total**	**1,250,500**	**1,334,800**	**n/a**	**n/a**	**n/a**
Unincorporated[6]		324,600	444,000	331,100	531,500	520,900

STATISTICS[1]	Year 2035 Projections			Build Out (2060) Projections	
	Riverside County RCP 2010[2]	SCAG RTP 2008[3]	Updated Gen. Plan Capacity[4,5,7]	Current Gen. Plan Capacity[7]	Updated Gen. Plan Capacity[4,5,7]
Incorporated	926,000	890,800	n/a	n/a	n/a
Employment Total	**1,285,300**	**1,413,500**	**n/a**	**n/a**	**n/a**
Unincorporated[6]	283,200	338,000	286,000	595,200	561,800
Incorporated	1,002,100	1,075,600	n/a	n/a	n/a

Footnotes:
1. All demographic values rounded to the nearest 100.
2. Riverside County Center for Demographic Research, Riverside County Projections 2010 (RCP-10).
3. SCAG, Regional Transportation Plan, 2008.
4. That is, the current General Plan as amended pursuant to the changes proposed by the project, GPA No. 960.
5. The growth rate for the updated General Plan is calculated as an average of the targeted years (2035 and 2060). As a result,the rate does not represent a compounding annual growth rate formula.
6. Values vary due to the effects of new city incorporations. The RCP-10 data set excludes the new cities of Wildomar and Menifee from the "unincorporated" data, the SCAG 2008 RTP does not.
7. Estimates not available because the Riverside County General Plan does not include incorporated areas.

Source: Riverside County Planning Dept., project application materials, 2010. Riverside County Center for Demographic Research, Riverside County Projections 2010 (RCP-10), 2010.

Additionally, comparing and analyzing data that utilize different assumptions is difficult. For instance, since the development of SCAG RTP-08, two new cities (Wildomar and Menifee) have been incorporated in Riverside County, a fact that is reflected in Riverside County's RCP-10 but not in SCAG's earlier RTP-08. A county like Riverside where economic tides directly affect the growth, it needs its socioeconomic data and land use plans adjusted regularly to efficiently manage both the growth pressure and the undulating economic conditions. This makes comparing regional data and assessing regional consistency even more difficult, as the official projection data from the regional entities become outdated. SCAG's official regional projection data for Riverside County at this point in time is the RTP-08. Therefore, having to compare RCP-10 data rather than the RTP-08 data with the General Plan land use remedies the issue of data inconsistency.

The usual approach for local jurisdictions in Riverside County is to compare SCAG's RTP-08 projections with the full build out of their general plans' land use plans. However, a quantitative comparison between the proposed updated General Plan and RCP-10, rather than SCAG's RTP-08, was determined to be more current and appropriate for assessing regional consistency, because the RTP-08 used pre-recession projections which have seen been revised downward to reflect the current economy. As an example from Table 5.6-A, the SCAG RTP-08 population projection for 2035 was 3.6 million while the RCP-10 population projection was only 3.4 million. The difference mainly comes from different base year conditions. SCAG's RTP-08 projections used 2006 Riverside County data (pre-recession), while RCP-10 used 2010 Riverside County data, which captures the economic downturn. Another consideration was the fact that the next set of SCAG projections would be released under the 2012 Regional Transportation Plan (RTP-12). The RTP-12 scenario developed by SCAG will use the most recent projections of its member counties; in this case, Riverside County submitted its RCP-10 projections to SCAG for their use. For these reasons, the updated General Plan build out scenario, as per GPA No. 960 proposed changes, was assessed for regional socioeconomic consistency using RCP-10 as the regional projections model rather than SCAG's 2008 RTP.

The other technical difficulty that arises in socioeconomic consistency assessments is the issue of comparing data with different projection years (that is, covering differing time spans). While the regional data projections available go to year 2035, the General Plan land use has an estimated build out year of 2060. This inconsistency was addressed in two ways: Since the numbers do not exactly cover the same timeframe, the first solution is to instead compare the overall capacity supply and demand trends for Riverside County's unincorporated areas. The second is to examine the respective jobs-to-housing unit ratios.

First, the purpose of the projection data is to analyze Riverside County's growth trends and factors for development into the future. In the case of RCP-10 and RTP-08, the forecasts project to the year 2035. Since this data predicts how Riverside County is going to grow in terms of population, dwelling units and employment, it can be equated to the demand factors for growth. Conversely, the General Plan's land use assumptions provide a geographical basis and association for Riverside County's forecast demographic values. The challenge of the General Plan then, is to ensure that this growth is managed and directed in a coordinated and appropriate manner for orderly development within Riverside County. For this reason, the land use assumptions of the General Plan can be considered as the supply factors that dictate where and how the County of Riverside would accommodate its portion of the forecasted regional growth. Since the proposed update for the General Plan integrated regional projection data into its land use planning assumptions, both supply and demand factors can be adequately addressed through a checks and balance system.

As shown in Table 5.6-A, at anticipated build out in 2060, the General Plan, as updated by GPA No. 960, would have the land use capacity to accommodate a population of roughly 1,702,700 residents, 520,900 housing units and 561,800 jobs. In order to compare the two numbers consistently at a given year of 2035, these General Plan build out numbers were interpolated (back-projected) to year 2035 by applying a steady annual growth rate. The resultant projections for year 2035 yielded a population of 969,100 with a corresponding 3% growth rate, 331,100 dwelling units with a 2.3-2.6% growth rate and 286,000 jobs value with a 4-5% growth rate. When compared to the same socioeconomic projections for RCP-10, the population, dwelling units and employment results only slightly exceed its 2035 projections: 6.6% higher for population, 2.0% higher for dwelling units and 1.0% higher for employment. Such close numbers demonstrates that the project-updated General Plan would be generally consistent with regional projections.

The other method for regional consistency comparisons mentioned above involves a comparison of the job-to-housing unit ratios. This ratio measures the extent to which job opportunities in a given geographic area match the available housing in the same area. This ratio highlights the basic planning premise that a "balanced" community provides a reasonable amount of both housing and jobs in close proximity, so that residents can both live and work in their local community – avoiding long commutes that trigger higher traffic, increase air pollution and noise, and generally decrease the overall standard of living. Accordingly, a commonly accepted "optimal balance" for a jobs-to-housing ratio is in the range of 1.3 or 1.4 jobs-to-housing units. That is, the number of employed persons (jobs) divided by the number of housing units available. A ratio in the 1.3 to 1.4 range would mean that there is a net surplus of jobs available, which would draw job-seekers into the community, rather than necessitate workers' exodus outward for employment. According to Ewing (1996), Cervero (1991) and others, a ratio in this range implies balance in the community.

The jobs-housing ratio of the updated General Plan at build out (2060) was calculated at 1.08 and at 0.86 for year 2035. This is nearly the same as that for RCP-10 (0.87), although the updated General Plan does provide a higher gross employment level (286,000 jobs) than RCP-10 (283,200 jobs). In addition, it is important to note that as growth in Riverside County proceeds from 2035 to 2060, the balance in the jobs-to-housing ratio for unincorporated Riverside County improves (from 0.86 in 2035 to 1.08 at 2060 build out). This is an indication that the proposed updated General Plan is improving Riverside County's jobs-housing balance over time. This is important as, historically, Riverside County has been a housing-rich region in need of additional local jobs to ensure proper balance. In particular, these ratios demonstrate that further increases in housing without corresponding increases in employment opportunities would only worsen Riverside County's balance and negatively affect the traffic patterns in Riverside County. As demonstrated in Table 5.6-A, the revisions to the General Plan proposed by GPA No. 960 help decrease the gap between housing and employment over time. The updated General Plan provides a blueprint for achieving an improved job-to-housing ratio over time, while at the same time maintaining consistency with SCAG regional plan for 2035.

For all of these reasons, the proposed project, as it affects Riverside County's General Plan, is considered regionally consistent at the demographic and socioeconomic level with both the RCP-10 and, since the RCP-10 will be used by SCAG in the preparation of its RTP-12, with future Regional Transportation Plans.

C. SCAG Regional Comprehensive Plan

As described by SCAG, its 2008 Regional Comprehensive Plan is a "major advisory plan" that addresses "important regional issues like housing, traffic / transportation, water and air quality." SCAG further states that:

> *"The Regional Comprehensive Plan (RCP) serves as an advisory document to local agencies in the Southern California region for their information and voluntary use for preparing local plans and handling local issues of regional significance. The RCP presents a vision of how Southern California can balance resource conservation, economic vitality and quality of life. The RCP identifies voluntary best practices to approach growth and infrastructure challenges in an integrated and comprehensive way. It also includes goals and outcomes to measure our progress toward a more sustainable region."*

Along with the quantitative regional analyses provided above, the 2008 SCAG Regional Comprehensive Plan also contains a number of policies that were analyzed qualitatively for regional consistency. In this subsection, the various applicable portions of the SCAG Regional Comprehensive Plan are listed and the consistency of the proposed updated General Plan relative to these policies is discussed.

The SCAG RCP features nine chapters, each of which include an "Action Plan" of numbered policies, called "SCAG Best Practices," to address specific areas of planning or resource management. Since many of the chapters in the RCP address SCAG operations or directives from the federal or state government, only those SCAG policies relevant to local governments, i.e., the County of Riverside, are addressed here. For each of the SCAG "Action Plans" addressed below, the relevant SCAG policies (i.e., "SCAG Best Practices") are first listed in italics, with a discussion of the project's consistency following.

1. Land Use and Housing Action Plan

LU-4: *Local governments should provide for new housing, consistent with State Housing Element law, to accommodate their share of forecast regional growth.*

LU-4.1: *Local governments should adopt and implement General Plan Housing Elements that accommodate housing needs identified through the Regional Housing Needs Assessment (RHNA) process. Affordable housing should be provided consistent with RHNA income category distributions adopted for each jurisdiction. To provide housing, especially affordable housing, jurisdictions should leverage existing State programs such as HCD's Workforce Incentive Program and density bonus law and create local incentives (e.g., housing trust funds, inclusionary zoning, tax-increment-financing districts in redevelopment areas and transit villages) and partnerships with non-governmental stakeholders.*

Discussion: The recently amended Housing Element of the General Plan identifies and establishes Riverside County's policies with respect to meeting the needs of existing and future residents in Riverside County. It establishes policies that guide County decision-making and it sets forth an action plan to implement housing goals as required for the SCAG region and to meet Riverside County's Regional Housing Needs Assessment share. The changes proposed by the project do not alter this outcome. According to the above discussion, the project-updated General Plan would be consistent with the land use and housing policies of the SCAG Regional Comprehensive Plan. GPA No. 960 does not propose any changes to General Plan policies that would contradict the SCAG Regional Plan or impede implementation of its policies.

LU-5: *Local governments should leverage federal and state and local funds to implement the Compass Blueprint.*

LU-5.1: *All stakeholders should leverage state infrastructure bond financing, including the Department of Housing and Community Development's Transit Oriented Development program and should support legislation that will target infrastructure bond funds for regions with adopted growth visions such as the Compass Blueprint and for projects consistent with these visions.*

LU-5.2: *Subregional organizations should leverage the federal transportation planning funds available at the subregional level, to complete projects that integrate land use and transportation planning and implement Compass Blueprint principles.*

Discussion: GPA No. 960 does not directly discuss the funding and financing of development projects. It does, however, provide for a uniquely integrated planning process that balances the needs of development with the infrastructure, particularly roadways, needed to serve the new uses through CETAP. The TUMF (Transportation Uniform Mitigation Fee) program further ensures this integration by requiring new development pay its fair share of funds needed to provide roadway and related infrastructure improvements when needed. GPA No. 960 would further contribute to this coordination by providing updates to the Circulation Element of the General Plan, including the Countywide Circulation Network. For these reasons, the updated General Plan, as amended pursuant to GPA No. 960, would be consistent with the land use and housing policies of the SCAG Regional Comprehensive Plan. GPA No. 960 does not propose any changes to General Plan policies that would contradict the SCAG Regional Plan or impede implementation of its policies.

LU-6: *Local governments should consider shared regional priorities, as outlined in the Compass Blueprint, Regional Transportation Plan and this Regional Comprehensive Plan, in determining their own development goals and drafting local plans.*

LU-6.1: *Local governments should take a comprehensive approach to updating their General Plans, keeping General Plans up-to-date and providing progress reports on updates and implementation, as required by law.*

Discussion: GPA No. 960 includes countywide and Area Plan-wide updates to policies and maps in the required and optional elements, as well as in the various appendices, to provide up-to-date data supporting the changes. For example, the Land Use Element contains policy areas and overlays with alternate land use assumptions that accurately calculate the density yields of the targeted areas, such as the Good Hope and Meadowbrook communities, to determine the maximum impact of the alternate land use designation. The Circulation Element contains updates to the roadway networks to reflect the latest traffic study results based on the future General Plan land uses. It also includes an updated comprehensive countywide trails network system. The Air Quality Element contains new policies to provide guidance on how to analyze Greenhouse Gas (GHG) emissions in Riverside County to be compliant with the AB 32 and SB 375 legislation targets through implementation of screening tables in the review process. The impacts of the each GPA No. 960 policy and map changes are discussed further in various relevant EIR sections.

LU-6.2: *Developers and local governments should integrate green building measures into project design and zoning such as those identified in the U.S. Green Building Council's Leadership in Energy and Environmental Design, Energy Star Homes, Green Point Rated Homes and the California Green Builder Program.*

LU-6.3: *Local governments and subregional organizations should develop ordinances and other programs, particularly in the older, more urbanized parts of the region, which will enable and assist in the cleanup and redevelopment of brownfield sites.*

Discussion: GPA No. 960 includes new GHG reduction measures that would substantially lessen the GHG emissions and cumulative impacts. Many of the reduction strategies that are applicable to the new development projects in Riverside County are consistent with U.S. Green Building Council's Leadership in Energy and Environmental Design, Energy Star Homes, Green Point Rated Homes and the California Green Builder

Program. The screening tables for GHG implementation measures in the proposed Climate Action Plan (CAP) include reduction guidelines for new residential developments and deals with various topics from insulations and appliances to renewable energies and water efficiency.

The above analysis indicates that implementation of GPA No. 960, would be consistent with the land use and housing policies of the SCAG Regional Plan. The proposed project and updated General Plan does not contain any policies that would contradict the SCAG Regional Plan or impede implementation of its policies.

2. Open Space and Habitat – Natural Lands Action Plan

OSN-12: *Local governments should track and monitor open space conservation by:*

- *Considering the most recent annual report on open space conservation in planning and evaluating projects and programs in areas with regionally significant open space resources.*
- *Ensuring consistency with the open space conservation policies and goals of the Regional Comprehensive Plan.*

OSN-13: *Local governments should develop and implement mitigation for open space impacts by:*

- *Promoting coordinated mitigation programs for regional projects and establish the basis for inter-regional conservation strategies.*
- *Planning development in locations least likely to cause environmental impact.*

OSN-14: *Developers and local governments should implement mitigation for open space impacts through the following activities:*

- *Individual projects should either avoid significant impacts to regionally significant open space resources or mitigate the significant impacts through measures consistent with regional open space policies for conserving natural lands, community open space and farmlands. All projects should demonstrate consideration of alternatives that would avoid or reduce impacts to open space.*
- *Individual projects should include into project design, to the maximum extent practicable, mitigation measures and recommended best practices aimed at minimizing or avoiding impacts to natural lands, including, but not limited to FHWA's Critter Crossings and Ventura County Mitigation Guidelines.*
- *Project-level mitigation for RTP's significant cumulative and growth-inducing impacts on open space resources will include but not be limited to the conservation of natural lands, community open space and important farmland through existing programs in the region or through multi-party conservation compacts facilitated by SCAG.*
- *Project sponsors should ensure that transportation systems proposed in the RTP avoid or mitigate significant impacts to natural lands, community open space and important farmland, including cumulative impacts and open space impacts from the growth associated with transportation projects and improvements.*
- *Project sponsors should fully mitigate direct and indirect impacts to open space resulting from implementation of regionally significant projects.*

Discussion: The current General Plan Multipurpose Open Space Element Chapter contains policies and plans to ensure conservation of regionally significant open space resources and contains policies to fully mitigate impacts to open space resulting from regionally significant projects. Since the adoption of the Riverside County General

Plan in 2003, the County of Riverside has been vigorously implementing the Western Riverside County Multiple Species Habitat Conservation Plan (WRC-MSHCP) which focuses on protecting 146 native species of plants and animals with their habitats while balancing growth and new development pressures. Riverside County, through the Regional Conservation Authority (RCA), is actively acquiring and preserving habitats for preservation. In 2007, the Coachella Valley Association of Governments (CVAG) adopted a similar conservation plan for the Coachella Valley Region of Eastern Riverside County named, the "Coachella Valley Multiple Species Habitat Conservation Plan" (CV-MSHCP). The two MSHCPs are comprehensive and multi-jurisdictional. They focus on the conservation of species, associated habitats and linkages to provide mitigation for the impacts of development in Riverside County. Together, the MSHCPs afford the County of Riverside the ability to manage local land use decisions and maintain economic development flexibility, while providing a coordinated conservation system and reserve implementation program.

As part of GPA No. 960, lands acquired by RCA in recent years are all changed to the General Plan land use designation of Open Space-Conservation Habitat (OS-CH). This designation aids in ensuring these lands are appropriately conserved for their biological functions and values. To the extent the project would have adverse effects on open space, these are discussed in Section 5.2.B (Significant Irreversible Environmental Changes) and, in particular, summarized in Table 5.2-A (Open Space Areas Proposed for Future Development Uses). Sections 4.8 (Biological Resources) and 4.16 (Parks and Recreation) in this EIR also discuss open space. Between the policies of the General Plan, particularly in the Multipurpose Open Space and Conservation Element, and the open space conservation achieved through implementation of the WR- and CV-MSHCPs, Riverside County's operations are consistent with the SCAG Regional Comprehensive Plan. Further, GPA No. 960 does not propose policies contradicting the SCAG Regional Plan nor would any of its proposals impede implementation of these SCAG open space policies.

3. Open Space and Habitat – Community Open Space Action Plan

OSC-7: *Local governments should prepare a Needs Assessment to determine the adequate community open space level for their areas.*

OSC-8: *Local governments should encourage patterns of urban development and land use, which reduce costs on infrastructure and make better use of existing facilities.*

OSC-9: *Developers and local governments should increase the accessibility to natural areas lands for outdoor recreation.*

OSC-10: *Developers and local governments should promote infill development and redevelopment to revitalize existing communities.*

OSC-11: *Developers should incorporate and local governments should include land use principles, such as green building, that use resources efficiently, eliminate pollution and significantly reduce waste into their projects, zoning codes and other implementation mechanisms.*

OSC-12: *Developers and local governments should promote water-efficient land use and development.*

OSC-13: *Developers and local governments should encourage multiple use spaces and encourage redevelopment in areas where it will provide more opportunities for recreational uses and access to natural areas close to the urban core.*

Discussion: The proposed Multipurpose Open Space Element Chapter of the General Plan includes new policies and plans to ensure accessibility to natural areas. GPA No. 960 proposes new trail network plans and policies to provide for an improved quality of life and access to natural open spaces for Riverside County residents. For instance in Lakeview/Nuevo and Reche Canyon/Badlands Area Plans, the new trail network

provides access points and routes within the Lake Perris State Recreation Area which does not exist in the existing General Plan. GPA No. 960 also includes proposed polices in water-efficient landscaping and development to bridge the gap between water supply and demand. For example, the proposed Open Space Element Policy 2.1 includes, "Implement a water-efficient landscape ordinance and corresponding policies that promote the use of water-efficient plants and irrigation technologies, minimizes the use of turf and reduces water-waste without sacrificing landscape quality". The policy also is accompanied by several implementation measures as outlined in the Appendix K-1 of the General Plan (AI 3, 57, 57B, 58, 62). Water efficient landscaping policies are included in both Land Use and Multipurpose Open Space Elements. These policies serve to reduce water-waste. The impact of GPA No. 960 is discussed further in EIR Section 4.14 (Mineral Resources). Riverside County will continue to implement and monitor existing ordinances and General Plan policies to reduce impacts from future development proposals.

The above analysis indicates that implementation of GPA No. 960 would be consistent with the open space and habitat policies of the SCAG Regional Plan. GPA No. 960 does not propose any General Plan policies or changes that would contradict the SCAG Regional Plan or impede implementation of its policies.

4. Open Space and Habitat – Agricultural Lands Action Plan

OSA-5: *Promote the availability of locally grown and organic food in the region.*

- *Local governments should establish transfer of development rights (TDR) programs to direct growth to less agriculturally valuable lands (while considering the potential effects at the sites receiving the transfer) and ensure the continued protection of the most agriculturally valuable land within each county through the purchase of the development rights for these lands.*
- *Local governments should consider other tools for the preservation of agricultural lands such as eliminating estates and ranchettes and clustering to retain productive agricultural land.*
- *Local governments should ease restrictions on farmer's markets and encourage cooperative farming initiatives to increase the availability of locally grown food.*
- *Local governments should consider partnering with school districts to develop farm-to-school programs.*

OSA-7: *Local governments should avoid the premature conversion of farmlands by promoting infill development and the continuation of agricultural uses until urban development is imminent; if development of agricultural lands is necessary, growth should be directed to those lands on which the continued viability of agricultural production has been compromised by surrounding urban development or the loss of local markets.*

Discussion: The Land Use, Administration and Healthy Communities Elements of the Riverside County General Plan include policies and plans to protect viable farmlands, manage agricultural lands in a growth pressured areas and encourage farmers markets. The impacts of GPA No. 960 on agricultural resources are discussed further in Section 4.5 (Agricultural and Forestry Resources) of this EIR. Despite programs that address the premature conversion of agricultural lands to urbanizing uses, Section 4.5 concludes that future developments accommodated by the land use and policies of the proposed General Plan Amendment could indirectly lead to the conversion of designated farmlands thus the impact of the project was found to be significant and unavoidable. Loss of agricultural lands to non-agricultural land uses designation is an indirect contributing factor of farmland conversion thus affecting the region as a whole and making the impact significant and unavoidable. Nonetheless, GPA No. 960 is consistent with the open space and habitat policies of the SCAG Regional

Comprehensive Plan and does not contain policies that would contradict the Regional Plan or impede implementation of its policies.

5. Water Action Plan

WA-9: *Developers and local governments should consider potential climate change hydrology and resultant impacts on available water supplies and reliability in the process of creating or modifying systems to manage water resources for both year-round use and ecosystem health.*

WA-10: *Developers and local governments should include conjunctive use as a water management strategy when feasible.*

WA-11: *Developers and local governments should encourage urban development and land uses to make greater use of existing and upgraded facilities prior to incurring new infrastructure costs.*

WA-12: *Developers and local governments should reduce exterior uses of water in public areas and should promote reduced use in private homes and businesses, by shifting to drought-tolerant native landscape plants (xeriscaping), using weather-based irrigation systems, educating other public agencies about water use and installing related water pricing incentives.*

WA-13: *Developers and local governments should protect and preserve vital land resources – wetlands, groundwater recharge areas, woodlands, riparian corridors and production lands. The federal government's "no net loss" wetlands policy should be applied to all of these land resources.*

WA-14: *Local governments should amend building codes to require dual plumbing in new construction and provide incentives for plumbing retrofits in existing development, to enable the safe and easy use of recycled water in toilets and for landscaping.*

WA-15: *Local governments should amend ordinances as necessary to allow municipal and private outdoor use of recycled water for all parks, golf courses and outdoor construction needs.*

WA-18: *Local governments should create stable sources of funding for water and environmental stewardship and related infrastructure sustainability, including purchase and implementation of green infrastructure.*

WA-20: *Local governments should use both market and regulatory incentive mechanisms to encourage "water wise" planning and development, including streamlining and prioritizing projects that minimize water demand and improve water use efficiencies.*

WA-21: *Local governments should develop comprehensive partnership approaches to remove and prevent water impairments, replacing the existing regulatory command and control approach that has created delays and distrust.*

WA-22: *Local governments should create opportunities for pollution reduction marketing and other market-incentive water quality programs.*

WA-23: *Local governments should encourage Low Impact Development and natural spaces that reduce, treat, infiltrate and manage runoff flows caused by storms and impervious surfaces.*

WA-24: *Local governments should prevent development in flood hazard areas lacking appropriate protections, especially in alluvial fan areas.*

WA-25: *Local governments should implement green infrastructure and water-related green building practices through incentives and ordinances.*

Discussion: The proposed Land Use, Administration, Safety and Multipurpose Open space Elements of the General Plan include policies and plans to ensure protection of viable water sources and wetlands, availability of water and its infrastructures, and reduction of water related hazards. GPA No. 960 adds stronger water-efficient landscape polices to ensure implementation of water-efficient plants and irrigation technologies to minimize water waste. Other policies regarding water quality and groundwater recharge have also been modified in the General Plan to include strategies incorporating "Low Impact Development" and other Best Management Practices. The new Water Resources section of the Land Use Element includes policies that address the issues between the water supply and demand in Riverside County while protecting natural resources of wetlands, arroyos and riparian corridors. In addition, GPA No. 960 includes most up-to-date countywide 100-year flood hazard zone maps and policies to limit potentially hazardous development and to require appropriate protections for such developments.

In addition, the current development review process adheres to the existing regulations at both the state and federal level. The California Water Code establishes the control of almost every aspect of water resource management within the state as a response to federal laws mandating state involvement. Counties must operate within the regulations established in the California Water Code in addition to other regulations such as the Clean Water Act, Federal Water Pollution Act, Water Conservation in Landscaping Act, and Urban Water Management Planning Act. With the existing federal, state and county regulations, as well as existing and proposed General Plan policies that will help ensure resources are appropriately identified and protected, GPA No. 960 is consistent with SCAG's Regional Water Action Plan policies. See EIR Sections 4.11, 4.17 and 4.19 for further discussion on project impacts in these areas.

The above analysis indicates that implementation of GPA No. 960 would be consistent with the water policies of the SCAG Regional Plan. Further, GPA No. 960 does not contain policies that would contradict the Regional Plan or impede implementation of its policies.

6. Energy Action Plan

EN-8: *Developers should incorporate and local governments should include the following land use principles that use resources efficiently, eliminate pollution and significantly reduce waste into their projects, zoning codes and other implementation mechanisms:*

- *Mixed-use residential and commercial development that is connected with public transportation and utilizes existing infrastructure.*
- *Land use and planning strategies to increase biking and walking trips.*

EN-9: *Local governments should include energy analyses in environmental documentation and general plans with the goal of conserving energy through the wise and efficient use of energy. For any identified energy impacts, appropriate mitigation measures should be developed and monitored. SCAG recommends the use of Appendix F, Energy Conservation, of the California Environmental Quality Act.*

EN-10: *Developers and local governments should integrate green building measures into project design and zoning such as those identified in the U.S. Green Building Council's Leadership in Energy and Environmental Design, Energy Star Homes, Green Point Rated Homes and the California Green Builder Program. Energy saving measures that should be explored for new and remodeled buildings include:*

- *Using energy efficient materials in building design, construction, rehabilitation and retrofit.*
- *Encouraging new development to exceed Title 24 energy efficiency requirements.*

- *Developing Cool Communities measures including tree planting and light-colored roofs. These measures focus on reducing ambient heat, which reduces energy consumption related to air conditioning and other cooling equipment.*
- *Utilizing efficient commercial/residential space and water heaters: This could include the advertisement of existing and/or development of additional incentives for energy efficient appliance purchases to reduce excess energy use and save money. Federal tax incentives are provided online at http://www.energystar.gov/index.cfm?c=Products.pr_tax_credits.*
- *Encouraging landscaping that requires no additional irrigation: utilizing native, drought tolerant plants can reduce water usage up to 60% compared to traditional lawns.*
- *Encouraging combined heating and cooling (CHP), also known as cogeneration, in all buildings.*
- *Encouraging neighborhood energy systems, which allow communities to generate their own electricity.*
- *Orienting streets and buildings for best solar access.*
- *Encouraging buildings to obtain at least 20% of their electric load from renewable energy.*

EN-11: *Developers and local governments should submit projected electricity and natural gas demand calculations to the local electricity or natural gas provider, for any project anticipated to require substantial utility consumption. Any infrastructure improvements necessary for project construction should be completed according to the specifications of the energy provider.*

EN-12: *Developers and local governments should encourage that new buildings are able to incorporate solar panels in roofing and tap other renewable energy sources to offset new demand on conventional power sources.*

EN-13: *Local governments should support only the use of the best available technology including monitoring, air and water impacts for locating any nuclear waste facility.*

EN-14: *Developers and local governments should explore programs to reduce single occupancy vehicle trips such as telecommuting, ridesharing, alternative work schedules and parking cash-outs.*

EN-15: *Utilities and local governments should consider the most cost-effective alternative and renewable energy generation facilities.*

EN-16: *Local governments and project implementation agencies should consider various best practices and technological improvements that can reduce the consumption of fossil fuels such as:*

- *Encouraging investment in transit, including electrified light rail.*
- *Expanding light-duty vehicle retirement programs.*
- *Increasing commercial vehicle fleet modernization.*
- *Implementing driver training module on fuel consumption.*
- *Replacing gasoline powered mowers with electric mowers.*
- *Reducing idling from construction equipment.*
- *Incentivizing alternative fuel vehicles and equipment.*

- *Developing infrastructure for alternative fueled vehicles.*
- *Increasing use and mileage of High Occupancy Vehicle (HOV), High Occupancy Toll (HOT) and dedicated Bus Rapid Transit (BRT) lanes.*
- *Implementing truck idling rule, devices and truck-stop electrification.*
- *Requiring electric truck refrigerator units.*
- *Reducing locomotives fuel use.*
- *Modernizing older off-road engines and equipment.*
- *Implementing cold ironing at ports.*
- *Encouraging freight mode shift.*
- *Limit use and develop fleet rules for construction equipment.*
- *Requiring zero-emission forklifts.*
- *Developing landside port strategy: alternative fuels, clean engines, electrification*

EN-19: *Subregional and local governments should explore participation in energy efficiency programs provided by their local utility such as the Ventura Regional Energy Office, South Bay Energy Savings Center and the San Gabriel Valley Energy Wise program. These programs can offer customized incentives and public awareness campaigns to reduce energy consumption.*

EN-20: *Local governments should employ land use planning measures, such as zoning, to improve jobs/housing balance and creating communities where people live closer to work, bike, walk and take transit as a substitute for personal auto travel.*

Discussion: The proposed updates to the General Plan's Land Use, Circulation and Air Quality Elements include policies and plans to reduce pollution and fossil fuel consumption through innovative measures designed to improve energy efficiency and energy conservation. There are also planning policies and strategies in the General Plan to integrate green building measures, encourage Transit Oriented Development (TOD) and achieve an appropriate balance between jobs and housing. For example, the updated comprehensive trails maps for Riverside County provide a network of connectivity that would increase the use of non-motorized transportation system. Additions to the Air Quality Element address greenhouse gases, but in doing so also provide strategies, regulations and policies applicable to all public and private residential, commercial, industrial and institutional developments.

The above analysis indicates that implementation of GPA No. 960 would be consistent with the energy policies of the SCAG Regional Plan. Further, GPA No. 960 does not propose any General Plan policies or changes that would contradict the SCAG Regional Plan or impede implementation of its policies. For additional details on the environmental impacts of the project in regards to energy, see Section 4.18 (Transportation and Circulation). The topic is also addressed in Section 4.7 (Greenhouse Gases), particularly as it relates to the energy conservation measures that would aid in achieving county greenhouse gas reduction goals.

7. Air Quality Action Plan

AQ-5: *Local governments should implement control measures from local Air Quality Management Plans (AQMPs) such as accelerating the turnover of older, more polluting mobile and stationary source equipment using AB 2766 funding per the State Implementation Plan (SIP).*

AQ-6: *Local governments should support and pursue environmentally sustainable strategies that implement and complement climate change goals and outcomes such as updating their General Plans to help address the State's AB 32 mandate. This should be consistent with state guidelines and requirements.*

AQ-7: *Local governments should develop policies that discourage the location of sensitive receptors that expose humans to adverse air quality impacts such as amending General Plans, zoning ordinances, business licensing and related land use permitting processes to minimize human health impacts from exposure of sensitive receptors to local sources of air pollution. Jurisdictions should consider applicable guidance documents, such as ARB's Air Quality and Land Use Handbook: A Community Health Perspective and the South Coast AQMD's Guidance Document for Addressing Air Quality Issues.*

AQ-8: *Local governments should practice and promote sustainable building practices by:*

AQ-8.1: *Updating their General Plans and/or zoning ordinances to promote the use of green building practices, which include incorporating LEED design standards and utilizing energy efficient, recycled-content and locally harvested or procured materials.*

AQ-8.2: *Developing incentive programs (e.g., density bonuses) to encourage green building and resource and energy conservation in development practices.*

AQ-8.3: *Adopting policies that strive for carbon neutrality for their own facilities and operations.*

Discussion: GPA No. 960 proposes changes to the Land Use, Circulation and Air Quality Elements of the Riverside County General Plan that include policies and plans to pursue environmentally sustainable strategies in achieving AB 32 goals and to promote sustainable building practices such as encouraging green building practices. Further, GPA No. 960 includes a technical study with GHG Emission inventories and emission reduction target plans as mandated by AB 32. This is the first step toward implementing workable policies that would achieve AB 32 visions and goals. The implementation measures with detailed screening tables of the aforementioned technical study will guide Riverside County's development review process in obtaining reduction targets.

The above analysis indicates that implementation of GPA No. 960, would be consistent with the air quality policies of the SCAG Regional Plan. Further, GPA No. 960 does not propose any General Plan policies or changes that would contradict the SCAG Regional Plan or impede implementation of its policies. For additional details on the environmental impacts of the project in regards to air quality, see Section 4.6 (Air Quality).

8. Solid Waste - Action Plan

SW-9: *Local governments should update general plans to reflect solid waste sustainability issues such as waste reduction goals and programs.*

SW-10: *Local governments should discourage the siting of new landfills unless all other waste reduction and prevention actions have been fully explored. If landfill siting or expansion is necessary, landfills should be sited with an adequate landfill-owned, undeveloped land buffer to minimize the potential adverse impacts of the landfill in neighboring communities.*

SW-11: *Local governments should discourage exporting of locally generated municipal solid waste (destined for landfills) outside of the SCAG region. Disposal within the county where the waste originates should be encouraged as much as possible, when appropriate. Green technologies for long-distance transport of waste (e.g., clean engines, clean locomotives or electric rail for waste-by-rail disposal systems) and consistency with AQMP and RTP policies should be required.*

SW-12: *Local governments should maximize waste diversion goals and practices and look for opportunities for voluntary actions to exceed the 50% waste diversion target.*

SW-13: *Local governments should build local markets for waste prevention, reduction and recycling practices.*

SW-14: *Developers and local governments should integrate green building measures into project design and zoning including, but not limited to, those identified in the U.S. Green Building Council's Leadership in Energy and Environmental Design, Energy Star Homes, Green Point Rated Homes and the California Green Builder Program. Construction reduction measures to be explored for new and remodeled buildings include:*

- *Reuse and minimization of construction and demolition (C&D) debris and diversion of C&D waste from landfills to recycling facilities.*
- *An ordinance that requires the inclusion of a waste management plan that promotes maximum C&D diversion.*
- *Source reduction through (1) use of building materials that are more durable and easier to repair and maintain, (2) design to generate less scrap material through dimensional planning, (3) increased recycled content, (4) use of reclaimed building materials, and (5) use of structural materials in a dual role as finish material (e.g., stained concrete flooring, unfinished ceilings, etc.).*
- *Reuse of existing building structure and shell in renovation projects. Building lifetime waste reduction measures that should be explored for new and remodeled buildings include:*
- *Development of indoor recycling program and space.*
- *Design for deconstruction.*
- *Design for flexibility through use of moveable walls, raised floors, modular furniture, moveable task lighting and other reusable components.*

SW-15: *Local governments should develop ordinances that promote waste prevention and recycling such as: requiring waste prevention and recycling efforts at all large events and venues; implementing recycled content procurement programs; and instituting ordinances to divert food waste away from landfills and toward food banks and composting facilities.*

SW-16: *Local governments should support environmentally friendly alternative waste management strategies such as composting, recycling and conversion technologies.*

SW-17: *Developers and local governments should develop and site composting, recycling and conversion technology facilities that are environmentally friendly and have minimum environmental and health impacts.*

SW-18: *Developers and local governments should coordinate regional approaches and strategic siting of waste management facilities.*

SW-19: *Developers and local governments should facilitate the creation of synergistic linkages between community businesses and the development of eco-industrial parks and materials exchange centers where one entity's waste stream becomes another entity's raw material by making priority funding available for projects that involve co-location of facilities.*

SW-20: *Developers and local governments should prioritize siting of new solid waste management facilities including recycling, composting and conversion technology facilities near existing waste management or material recovery facilities.*

SW-21: *Local governments should increase education programs to increase public awareness of reuse, recycling, composting and green building benefits and raise consumer education issues at the county and city level and if appropriate, at local school districts and education facilities.*

Discussion: GPA No. 960 does not include new land use policies or plans that are directly related to SCAG's Solid Waste Action Plan. Indirectly, however, GPA No. 960 does include a screening table for GHG reduction target implementation strategies which promote diversion of solid waste through recycling and site composting. The current policies in place with the Riverside County Solid Waste Management Plan will ensure that the solid waste sustainability issues are addressed appropriately. The full impact of the proposed General Plan in relation to solid waste management is discussed further in Section 4.15.3 (Solid Waste Management) of this EIR.

Overall, the above analysis indicates that implementation of GPA No. 960 would be consistent with the solid waste policies of the SCAG Regional Plan. Further, GPA No. 960 does not propose any General Plan policies or changes that would contradict the SCAG Regional Plan or impede implementation of its policies.

9. Other Action Plans in the SCAG Regional Comprehensive Plan

Transportation Action Plan, Security and Emergency Preparedness Action Plan and the Economy Action Plan in the Regional Comprehensive Plan contain only policies that affect SCAG directly. As none are applicable to the proposed project or updated General Plan, they are not further discussed here. For a discussion of the project's relationship to the SCAG Regional Transportation Plan (a separate plan from the RCP), see Section 4.18 (Transportation and Circulation). Emergency preparedness at the General Plan level is discussed in Section 4.13 (Hazardous Materials and Safety).

10. Regional Consistency Conclusions

GPA No. 960 includes ample policies that are consistent in achieving the goal outlined by SCAG's Regional Plan, which is to "foster a Southern California region that addresses future needs while recognizing the interrelationship between economic prosperity, natural resource sustainability and quality of life." A number of policies existing in the General Plan or proposed as part of GPA No. 960 are either identical or supplemental to the action plans items in the SCAG Regional Plan. Taken together, the above analyses indicate that implementation of GPA No. 960 would be consistent with the applicable policies of the SCAG Regional Plan. Further, GPA No. 960 does not contain policies that would contradict the SCAG Regional Plan or that would impede implementation of its policies.

D. SCAG Compass Southern California

In June 2004, SCAG issued a Growth Vision Report for its "Compass Southern California," to encapsulate its "growth visioning" efforts throughout the region. The underlying goal of this effort is to "make the SCAG region a better place to live, work and play for all residents regardless of race, ethnicity or income." Towards this

end, four "growth visioning principles" were developed to "promote and maximize regional mobility, livability, prosperity and sustainability." These are outlined, below.

1. SCAG Compass Principles

As a constituent member of SCAG, the County of Riverside is also working toward furthering these same quality of life goals for its residents and visitors. The General Plan is Riverside County's chief tool in guiding the region's growth in achieving these goals. For each of these SCAG principles and associated policies, a discussion is provided on how the proposed project relates to both Riverside County's General Plan and its use as a tool in accomplishing these universal principles.

Principle 1: Improve mobility for all residents.

- Encourage transportation investments and land use decisions that are mutually supportive.
- Locate new housing near existing jobs and new jobs near existing housing.
- Encourage transit-oriented development.
- Promote a variety of travel choices.

Discussion: The existing Riverside County General Plan contains numerous policies and directives that focus on improving mobility. In particular, the Circulation Element contains circulation plans and policies aimed at ensuring an efficient transportation system is developed and maintained within Riverside County. It also coordinates with the Land Use Element in addressing, and encouraging, transit-oriented development, trails networks, pedestrian connectivity and walkability in communities. Changes included in GPA No. 960 would further this effort by refining and improving circulation network plans, as well as by revamping the trails network map and standards. As such, GPA No. 960 is consistent with Compass Principle #1 and does not conflict with the policies stated above.

Principle 2: Foster livability in all communities.

- Promote infill development and redevelopment.
- Promote developments that provide a mix of uses.
- Promote "people-scaled," pedestrian-friendly communities.
- Support the preservation of stable, single-family neighborhoods.

Discussion: The Land Use Element of the existing Riverside County General Plan contains numerous policies and directives for promoting mixed use, infill development and pedestrian-friendly communities. The new Rural Village Overlays for Meadowbrook and Good Hope, as well as the Lakeland Village plans, would further improve the plans for future development in these urbanizing areas, including infill amongst existing uses. Similarly, removing study areas from rural communities not fully ripe for urbanization would further ensure infill and urban development continues to be concentrated in the more developed portions of Riverside County. GPA No. 960 also includes a new Lakeview Mountains Policy Area that would further emphasize the development of a pedestrian-friendly community through the principles of "new urbanism" and incorporate a trails network that

would connect urban uses within the community to public open space areas. GPA No. 960 is consistent with Compass Principle #2 and does not conflict with the policies stated above.

Principle 3: Enable prosperity for all people.

- Provide a variety of housing types in each community to meet the housing needs of all income levels.
- Support educational opportunities that promote balanced growth.
- Ensure environmental justice regardless of race, ethnicity or income class.
- Support local and state fiscal policies that encourage balanced growth.
- Encourage civic engagement.

Discussion: The existing Riverside County General Plan contains numerous policies and directives aimed at ensuring an appropriate mix of housing, including housing for all income levels, is provided within Riverside County. The General Plan Housing Element addresses this issue in detail. Policies throughout the General Plan, and particularly in the Land Use Element, address the need for providing balanced growth. GPA No. 960 would ensure this continues to be the case. As such, GPA No. 960 is consistent with Compass Principle #3 and does not conflict with the policies stated above.

Principle 4: Promote sustainability for future generations.

- Preserve rural, agricultural, recreational and environmentally sensitive areas.
- Focus development in urban centers and existing cities.
- Develop strategies to accommodate growth that use resources efficiently, eliminate pollution and significantly reduce waste.
- Utilize "green" development techniques.

Discussion: The Multipurpose Open Space Element of the existing Riverside County General Plan contains numerous policies and directives designed to ensure that Riverside County's natural and open space resources are preserved and protected. It also addresses the conservation of energy, water and other resources. The Land Use Element contains policies to focus development in urban centers, community centers and other appropriate areas. As part of GPA No. 960, the General Plan's Air Quality Element would be revised to address the reduction of greenhouse gas emissions through energy conservation, alternative energy use, and a variety of "green" development techniques. As such, GPA No. 960 is consistent with Compass Principle #4 and does not conflict with the policies stated above.

2. SCAG Regional Consistency Conclusion

Overall, the above analysis indicates that implementation of the updated General Plan, as amended pursuant to GPA No. 960, would be consistent with the policies of the SCAG Compass Southern California program, including its "Growth Visioning" principles. The proposed project and updated General Plan does not contain

any policies contradict these principles nor any that would impede implementation of its policies or attainment of its goals.

Section 6.0

Alternatives Analysis

Section 6.0 Alternatives Analysis

6.1 Introduction

One of the cornerstone functions of CEQA is that it "establishes a duty for public agencies to avoid or minimize environmental damage where feasible" (California Code of Regulations [CCR] Section 15021(a)). Accordingly the State CEQA Guidelines (CCR Section 15021(a)(2)) specify that, "A public agency should not approve a project as proposed if there are feasible alternatives or mitigation measures available that would substantially lessen any significant effects that the project would have on the environment."

The second part of this directive is met by Sections 4.2 through 4.19 of this EIR, which address a wide variety of environmental issues and include mitigation measures where feasible to lessen identified significant impacts. The first part of this directive, to identify "feasible alternatives" to the project, is addressed here. This section sets forth the criteria used to develop a "reasonable range of alternatives" and then analyzes the resultant alternative scenarios. Lastly, Section 6.0 concludes with an assessment of the "environmentally superior alternative" and analysis of each alternative's ultimate feasibility compared to that of the proposed project, GPA No. 960.

6.2 Selection of Alternatives

This subsection addresses the criteria used in establishing the range of alternatives to be analyzed.

A. CEQA Standards

The State CEQA Guidelines (CCR Section 15126.6(a)) specify that an EIR "shall describe a range of reasonable alternatives to the project" that would, "Feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the proposed project, and evaluate the comparative merits of the alternatives." In regards to the selection of alternatives to be analyzed, it goes on to further specify that:

> *"An EIR need not consider every conceivable alternative to a project. Rather it must consider a reasonable range of potentially feasible alternatives that will foster informed decision-making and public participation." "There is no ironclad rule governing the nature or scope of the alternatives to be discussed other than the rule of reason."*

Accordingly, CCR Section 15126.6(c) outlines the criteria for the "selection of a range of reasonable alternatives." It specifies that they shall include those that could do both of the following:

1. "Feasibly accomplish most of the basic objectives of the project."

2. "Avoid or substantially lessen one or more of the [project's] significant effects."

The discussion below sets out the selection factors that apply according to these conditions. First, the project's objectives are reiterated. Second, project impacts found to be significant in Section 4.0 are summarized and assessed for their relevance to the selection of alternatives.

B. Project Objectives

As noted in Section 3.0 (Project Description), the Riverside County General Plan is intended to be a blueprint for Riverside County's future. It describes the future growth and development planned within Riverside County over the long-term. Among its many features, the 2003 RCIP General Plan (as amended) includes a "Certainty System," designed to limit drastic changes to key land use patterns. (Specifically, it limits the redesignation of land uses to densities or intensities beyond those permitted by the "Foundation" established for a given parcel. See General Plan pages LU-38 to LU-42 for details.)

Also under the Certainty System, the County of Riverside is required to periodically review the General Plan and examine whether the established Foundation and land use designations remain appropriate. The first review was triggered five years after the 2003 adoption of the RCIP General Plan. Per the current General Plan Administrative Element, subsequent reviews are to occur every eight years thereafter. Thus, the primary goal of GPA No. 960 is to comprehensively review and update the County General Plan so that it continues to provide a clear, relevant and consistent set of directions for implementing the County Vision, General Plan Elements and individual Area Plans over the next eight years and into the future. A detailed description of the proposed updates, revisions and changes encompassed by this project, as permitted under the Certainty System, is provided in Section 3.0 of this EIR.

Pursuant to the Certainty System (and condensed from those set forth in Section 3.0), the proposed project, GPA No. 960, was undertaken to achieve the following objectives:

- Assess General Plan progress and issues related to its implementation: Ensure that the General Plan continues to provide a clear and consistent set of directions for implementing the Riverside County Vision throughout Riverside County over the next five to ten years and into the future (2035 and beyond).

- Initiate necessary changes among Foundation Components within the General Plan: Ensure that the land use direction and planned intensities remain appropriate for their given locations. Likewise, ensure that Policy Areas, Study Areas and Overlays throughout Riverside County continue to plan for coordinated development at appropriate intensities in the manner envisioned in the General Plan.

- Develop policy, entitlement and technical amendments, as warranted: Update or correct mapping items in the General Plan found to be inconsistent or inappropriate. Ensure that resource maps and other data-based information in the General Plan accurately reflect current data. Update the General Plan to accurately reflect current statutes, regulations and policies of the County of Riverside and applicable outside agencies. Update General Plan policies where necessary to reflect these items and to provide additional guidance where found to be necessary.

- Update future projections: Extend planning projections another five to ten years into the future and adjust the General Plan to accommodate previously unanticipated needs.

- Reassess the General Plan's Vision and Planning Principles: Recommit to and further the General Plan Vision and Planning Principles through the addition of policies and plans that expand upon them.

The manner in which these objectives were used in the selection of alternatives is discussed further below.

C. Significant Environmental Effects Associated With the Project

As outlined in Table 1.0-B of Section 1.0 (Summary), implementation of the General Plan pursuant to the changes proposed by GPA No. 960 would be associated with a number of significant and unavoidable environmental impacts. The various significant effects are briefly summarized in Table 5.0-A (Unavoidable Significant Environmental Effects) in Section 5.0 (Additional Required CEQA Topics). The analysis provided in Sections 4.2 through 4.19 of the EIR determined that the following impacts would remain significant even after the imposition of all feasible mitigation, namely: loss of State-designated farmlands and agricultural encroachment; short-term and long-term emissions of air pollutants, cumulative air pollutant impacts and exposure of sensitive receptors to air pollutants; exposure to excessive noise levels, as well as increases in both temporary and permanent ambient noise levels; increased traffic; insufficient water supplies, groundwater depletion and overdraft; and, lastly, a host of cumulative and growth-inducing impacts. See Tables 5.0-A and 5.0-B for full listings.

D. Screening of Possible Alternatives

The range of alternatives required in an EIR is governed by a "rule of reason" (CCR Section 15126.6(f)) that requires the EIR need only "set forth those alternatives necessary to permit a reasoned choice" among those alternatives that could "feasibly attain most of the basic objectives of the project" and would "avoid or substantially lessen any of the significant effects of the project."

1. Criteria for Project Objectives

Accordingly, the following criteria were used to ascertain if a proposed alternative sufficiently addressed the objective listed.

- **Further Progress:** An alternative would successfully meet this objective if it ensures the General Plan remains suitable as a plan for the coordination of future growth within Riverside County (for example, provides additional policies and plans, such as new Rural Village Overlays, where warranted to appropriately handle emerging growth patterns).

- **Update Land Use:** An alternative would successfully meet this objective if it provides updates to land use designations and Foundational components where necessary to ensure that the General Plan remains suitable as a plan for the coordination of future growth within Riverside County (for example, change mapped land use designations [LUDs] and Foundations where warranted to appropriately handle emerging growth patterns).

- **Update Technical Data:** An alternative would successfully meet this objective if it provides updates to General Plan's technical information (e.g., resource mapping, regulations, demographics and statistics, etc.) where necessary to ensure that the General Plan continues to accurately reflect the current environmental, regulatory, socioeconomic and development status of Riverside County (for example, updating General Plan maps to reflect newly released mineral data from the State of California and adding a forest resources map to better coordinate with new CEQA policies addressing forest resources).

- **Address New Needs:** An alternative would successfully meet this objective if it provides updates to the General Plan that enable it to appropriately plan, coordinate and implement new policies and programs necessitated by regulatory changes or by previously unanticipated needs (for example, adding greenhouse gas and climate change policies to the General Plan Air Quality Element in response to California State directives aimed at reducing carbon emissions).

- **Further County Vision:** An alternative would successfully meet this objective if the changes it proposes serve to enhance and extend the continued progress of the General Plan in achieving the long-range goals established in the Riverside County Vision (for example, the addition of the "Healthy Communities" Element to the General Plan to encourage healthy living enabled by appropriate patterns of development).

2. Range of Project Alternatives

Accordingly, a range of possible alternatives were developed to reflect the above project objectives and project significant impacts. The selection process is summarized in Table 6.0-A (Screening Table for Alternatives Considered), below, for the following basic alternative proposals.

Added Community Centers Alternative: This alternative addresses the effects of growth and development pressure by proposing to transfer development intensity planned for lands identified for future open space conservation into a series of additional community centers along transportation corridors. The overall number of residential units projected for unincorporated Riverside County would remain the same, but their locations, and possibly their densities, would change.

Agricultural Emphasis Alternative: This alternative addresses the effects of development pressure on agricultural resources by proposing a scenario in which removal of land from the Agricultural Foundation would only be allowed every eight years. Within the Eastern Coachella Valley Area Plan, future conversions would be limited to 50% of the proposed site; the remainder of the site would be required to be placed into permanent agricultural easements.

Reduced Rural Villages Alternative: This alternative would be similar to the changes to Rural Village Overlays (RVOs) proposed under GPA No. 960 in terms of eliminating RVO study areas (RVOSAs). However, it would also include additional reductions in development potential through the deletion of the two new RVOs proposed as part of GPA No. 960. Specifically, both the existing "Study Area" designations and the proposed new RVOs for the Good Hope and Meadowbrook areas would be deleted. Land uses would remain in their existing LUDs, with no alternative development potential added through the RVO overlay function. Unlike GPA No. 960, it would also omit several Policy Areas (either existing or proposed under GPA No. 960) that provide for future urbanization within specific areas, including in Anza in the hills of southern Riverside County and the Vista Santa Rosa region in the Coachella Valley, among others.

Green Economy Alternative: This alternative would entail revisions to the General Plan to encourage the development and utilization of the green (renewable) energy resources available in unincorporated Riverside County (e.g., wind, solar and geothermal). It would allow the transfer of development density/intensity from lands of high fire hazard into areas with alternative energy availability. The overall number of residential units and business uses (commercial and industrial) projected for unincorporated Riverside County would remain the same, but their locations, and possibly their densities, would change.

No Build/No Growth Alternative: This alternative is one type of "no project" scenario addressed by CEQA for comparison purposes. It would entail no growth occurring at all within unincorporated Riverside County (i.e.,

the County of Riverside would not approve any additional development applications). The only growth occurring in Riverside County would be within its cities, which are assumed to build out according to their General Plans. As a result, the environmental baseline of Riverside County would be preserved in many areas, except where adversely affected by the growing demands of the cities within Riverside County (e.g., water use, traffic generation, land annexations, etc.).

No Project/Status Quo Alternative: This alternative is the key CEQA-mandated "no project" alternative called out in CCR Section 15126.6(e). For this EIR, the scenario assumes that GPA No. 960 is not adopted and that the existing RCIP General Plan (adopted in October 2003, and as amended through 2010), remains the guiding document dictating future growth within unincorporated Riverside County. Accordingly, this alternative can also be said to represent the "status quo."

Privately Adjusted Development Alternative: This alternative would encompass the various property-owner initiated foundational General Plan Amendments proposed for the initial five-year cycle of changes. In this alternative, the General Plan would be revised to reflect the LUD and Foundation revisions proposed in a variety of prior GPAs and the existing General Plan Vision would be amended to place greater priority on property owner desires. The existing Vision's framework for development, transportation network and habitat conservation would be revised to reflect a more individual property rights-centered, less conservation-driven Vision.

Table 6.0-A: Screening Table for Alternatives Considered

Possible Alternatives [1]	Objectives Addressed	Further Progress	Update Land Use	Update Tech. Data [2]	Address New Needs [2]	Further County Vision	Impacts Addressed[3]	Agricultural	Air Quality	Noise	Transport. and Traffic	Water Supplies	Growth Inducement	Cumulative Effects	New Significant Effects?	Screening Outcome	Analyze	Reject
No Build / No Growth Alternative [4] *No build out in unincorporated Riverside County; only the cities are planned for growth*				•				o	o	o	◊[7]	◊[7]	o		◊[8]		•	
No Project / Status Quo Alternative [5,6] *Riverside County builds out per existing General Plan*				•					◊	◊	◊[7]	◊[7]		◊	◊[9]		•	
Agricultural Emphasis Alternative *Preserve agricultural lands through limits on their conversion to non-agricultural uses*				•	•			o		•	o	◊	•	◊	◊[10]		•	
Added Community Centers Alternative *Transfer development potential from Open Space to new Community Centers*		•		•	•	•		o			◊	◊		◊	◊[11]		•	
Green Economy Alternative *Transfer development potential to foster alternative energy use*		•	•	•	•	•		o			◊		◊		◊[12]		•	
Reduced Rural Villages Alternative *Eliminate the two RVOs proposed in GPA No. 960 (Good Hope and Meadowbrook RVOs)*			•	•					•	•	o	•	•	•	◊[13]		•	
Privately-Adjusted Development Alternative *Land use and General Plan Vision revised per property owner requests*				•	•													•

Footnotes:
1. See text for additional details on each of these possible alternatives.
2. Essentially, it is assumed that any alternative General Plan Amendment proposed could include these changes. Where no GPA is specifically proposed for an alternative, it is assumed that the updates indicated would occur through separate means (e.g., their own GPAs).
3. A dot (•) indicates the alternative addresses (i.e., lessens) the impact. A diamond (◊) denotes an impact that is substantially greater (worse) for the alternative than for the General Plan as updated per GPA No. 960. A circle (o) indicates the impacts would be avoided or substantially lessened under the alternative.
4. This is the "No Build" alternative mentioned in the State CEQA Guidelines (CCR Section 15126.6(e)(3)(B)).
5. This is the "No Project" alternative; its analysis is required pursuant to CEQA (i.e., see CCR Section 15126.6(e)).

6. Note, the existing General Plan includes greater future development potential than that proposed under GPA No. 960.
7. Would not accomplish improvements necessary for current or anticipated future deficiencies.
8. New significant impacts would also arise for: greenhouse gas emissions; and, energy inefficiency.
9. New significant impacts would also arise for: aesthetics/visual resources; greenhouse gas emissions; biological resources; and, energy inefficiency.
10. New significant impacts would also arise for: greenhouse gas emissions; and, energy uses (electricity and natural gas).
11. New significant impacts would also arise for: greenhouse gas emissions; and, growth effects on existing park and recreational facilities, including causing the need for new or expanded facilities.
12. New significant impacts would also arise for: aesthetics and viewshed changes; and, greenhouse gas emissions.
13. New significant impacts would also arise for: substantial indirect growth inducement in cities and adjacent counties.

Source: Riverside County Planning Department, project application and analysis from Section 6.0 of this EIR.

6.3 Rejected Alternatives

Pursuant to the State CEQA Guidelines (CCR Section 15126.6(c), the EIR must describe the "rationale for selecting the alternatives to be discussed," as well as "identify any alternatives that were...rejected as infeasible." Per this same section, factors that may be used to eliminate alternatives from "detailed consideration in an EIR" are:

- Failure to meet most of the basic project objectives.
- Infeasibility.
- Inability to avoid significant environmental impacts.

After initial analysis of each potential alternative's basic suitability, as shown in Table 6.0-A, the following alternatives were rejected for the reasons stated.

A. Privately-Adjusted Development Alternative

As described previously, this alternative would include all of the property owner-initiated General Plan Foundation amendment (GPA-F) requests made for the first periodic General Plan review and update. These foundation amendment requests were predominantly driven by individual property owners' desires and not necessarily guided by Riverside County's Vision as identified in the General Plan.

Objectives: In analyzing this proposed alternative relative to the stated project objectives (see Table 6.0-A), it was concluded that it would only satisfy two (40%) of the five outlined objectives. The attainment of these objectives would mainly be due to the fact that was assumed that components of GPA No. 960 were also to be included in this alternative (that is, the "update technical data" and "address new needs" objectives would be met through performing technical mapping, data and regulatory updates similar to those proposed for GPA No. 960). The alternative itself would not inherently address these issues without this assumption.

Environmental Impacts: Taken in its entirely, this alternative would result in uncoordinated and possibly "leap-frog" development since its items are based on individual development requests/ proposals, rather than dictated by the overarching policies, plans and development patterns established in the General Plan. As a result, build out of Riverside County according to this alternative would be estimated to result in significant adverse impacts to agriculture (loss of important farmlands), open space (development of currently vacant lands), air quality (increased air pollution), biology (loss of habitat), traffic (increased local and regional traffic), water supply (increased demand and groundwater degradation), among others. As a result, this alternative was rejected as unsuit-

able as it exacerbates, rather than eases, the significant impacts of GPA No. 960 and does not further the objectives of this update.

Consistency: This alternative would not address or provide clarity on policies of the existing General Plan for orderly and responsible growth, as GPA No. 960 proposes. The Vision Statement of the current General Plan discusses new growth patterns that follow a framework of transportation and open space corridors, with development fitting into that framework. Because of its individual request-driven nature, implementation of this alternative would promote a pattern of random sprawl and leap-frog development within Riverside County. It would not facilitate the orderly development and growth of Riverside County as identified as one of the fundamental functions of the General Plan. For all of these reasons, this alternative was found infeasible and rejected for further analysis in this EIR section. Note: these proposals are, however, still included as part of the cumulative scenario analyzed in Section 5.5 (Cumulative Impacts).

B. Offsite Alternatives

In addressing the type of "alternatives to the proposed project" to be considered, CEQA Section 15126.6(a) specifies that, "An EIR shall describe a range of reasonable alternatives to the project, *or to the location of the project*, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project" [emphasis added].

Since the scope of GPA No. 960 spans the breath of the General Plan, the "project area" is the entire unincorporated county, i.e., those lands under the jurisdictional authority of the County of Riverside and subject to the Riverside County General Plan. As such, no offsite alternatives are feasible, thus none are directly proposed or analyzed in this section.

However, it should be noted that one alternative does, in fact, *indirectly* address an offsite option. The No Build/No Growth alternative proposes a scenario in which no new development is approved in the unincorporated portions of Riverside County. As such, all development occurring in Riverside County would be within the cities, which are assumed to build out according to their individual General Plans. In addition to satisfying certain other CEQA requirements, the use of this type of "No Project" alternative allows an examination of the effects to "offsite" areas, namely the cities, as well as adjacent counties and their cities. See Section 6.4.A for the full description and analysis of the No Build/No Growth alternative.

6.4 Alternatives Analyzed

With the rejection of one potential alternative from consideration, a total of six different alternative project scenarios remain. These six were subjected to a more robust analysis to address the pros and cons of each relative to both the environment and the objectives of the proposed project, GPA No. 960. After each alternative was analyzed, the final determinations as to: a) which among them is the environmentally superior alternative; and, b) whether any among them is the preferred alternative (instead of the proposed project, GPA No. 960) for achieving build out of the General Plan. See Section 6.5 for these conclusions.

To facilitate the analysis of the alternatives, two types of "no project" alternative are addressed. They are both included in the fully analyzed alternatives even though neither of them meet more than one of the five project objectives. Among other things, the importance of these alternatives is that they inherently provide "baseline" values against which the effects of future build out can be compared. Specifically, the No Build/No Growth alternative starts with land use and demographic assumptions that are essentially the same as the baseline existing

condition assumptions used throughout the rest of this EIR. (For more background on how this was prepared, see the discussion in Section 5.5 on the "existing uses" scenario.) It then posits a future in which only the cities within Riverside County and no new development occurs in the unincorporated areas.

The importance of this scenario is that it shows how much growth and what environmental effect, for example, can be expected to occur despite any actions taken by the County of Riverside. Also, the project, GPA No. 960, and all of the other alternatives assume that the cities within Riverside County, as well as the cities and counties adjacent to Riverside County, do grow in this same fashion. As such, the effects attributable to just the cities and other non-county areas can be subtracted out from the overall effects of the project and each of the other alternatives. The results of such calculations indicate the contributions attributable solely to the unincorporated portions of Riverside County, i.e., the areas covered by the General Plan and addressed by GPA No. 960.

In a similar manner, the projections of the No Project/Status Quo alternative by definition represent the future build out associated with the existing General Plan since it assumes that the project does not occur. (Note, it is equivalent to the CURR GP scenario analyzed in Section 5.5.) The build out projections associated with this alternative also reflect the currently predicted future of Riverside County (as well as accounting for the growth/ build out of its cities and the surrounding counties, as described previously). As such, the proposed project and the other alternatives can each be compared against this scenario's outcomes to determine whether each would have greater or lesser effects compared to the existing General Plan. These plan-to-plan comparisons allow the relative merits and weaknesses of each alternative, as well as the proposed project's, to be ascertained. (The proposed project discussed in this section is generally equivalent to the GPU/GPA960 scenario analyzed in the cumulative impacts; see Section 5.5.)

Because of the importance of the two "no project" alternatives as analytical tools, they are presented first in this subsection. Following them are the remaining five alternatives. For each, a number of topics are addressed, including: the assumptions used to develop the alternative, including its starting (baseline) conditions, as well as the growth (build out) project to result; predictions for the alternative's effects on land use and socioeconomics at build out; predictions as to the severity of the alternative's expected environmental impacts (as compared to the baseline of the existing conditions in the county and region); the comparative effects of the alternative, including the severity of its environmental effects relative to the proposed project's; and the effectiveness of the alternative in meeting project objectives and its consistency with the existing General Plan's Visions and policies. And, lastly, the alternative's overall suitability for furthering the implementation and utility of the General Plan, and its overall merit relative to that of the proposed project.

General Assumptions: The alternatives developed for analysis herein were all developed from the same basic starting point. Thus, the common assumptions applied to all of alternatives are listed below. Where an alternative differs from these, they are described more fully under the specific affected alternative.

- Each alternative is based on the existing (2008) Riverside County General Plan, as amended pursuant to the alternative's unique individual revisions and changes.

- The incorporated cities within Riverside County continue to grow and build out pursuant to their individual General Plans. In order to maintain consistency among the various alternatives, no future annexations of unincorporated lands into the various cities are included in these alternatives. Also, it is assumed development within the cities' spheres of influence would occur as per the existing Riverside County General Plan, since such areas would remain part of unincorporated Riverside County.

- Within unincorporated Riverside County, the construction of necessary new or improved infrastructure will occur, as necessary to serve growing areas. This includes improvements to roadways (which would

be developed according to the 2008 countywide circulation network plan, i.e., General Plan Figure C-1), water conveyance and sewer treatment facilities, and regional flood control.

- GPA No. 960 (the proposed project) would not be approved. The technical and regulatory updates needed for the General Plan (e.g., statistical updates, resource mapping revisions, regulatory changes, etc.), however, would be adopted. No alterations to the General Plan's existing land use policies or maps would occur, other than those outlined for the given alternative.

- It is assumed that the existing General Plan is updated to discuss climate change and greenhouse gas (GHG) regulation. Unless stated otherwise for a given alternative, the draft Climate Action Plan (CAP) included with GPA No. 960 is assumed to be adopted and implemented.

- Implementation of the Western Riverside Multiple Species Habitat Conservation Plan (MSHCP) and the Coachella Valley MSHCP are assumed to continue.

- Riverside County DIF and TUMF programs are assumed to continue as programmed for county roadway improvements. TUMF improvements within Riverside County would reflect those identified in the existing General Plan (or alternative, as applicable).

- It is assumed that the circulation networks within Riverside County (including the cities), as well as those of the surrounding cities and counties, would generally be improved as planned for by the individual existing general plans and regionally as planned for by the 2008 Regional Transportation Plan (RTP) adopted by the Southern California Association of Governments (SCAG) to coordinate regional circulation amongst the counties and cities of Southern California (specifically, the counties of Riverside, San Bernardino, Orange, Los Angeles and Ventura, and their internal cities). Similarly, it is assumed that the state (Caltrans) and federal agencies (e.g., Federal Highway Administration, FHWA) would continue to perform improvements to the state and federal highways passing through unincorporated Riverside County.

- For the regions outside the boundaries of Riverside County, land use and demographic assumptions used are those promulgated by SCAG for the six-county region, for example, the SCAG 2012 RTP. It should be noted that both the existing General Plan and proposed updates of GPA No. 960 use and incorporate a set of socioeconomic projections developed for the county by the Riverside County Center for Demographic Research (RCCDR) and approved by the Riverside County Board of Supervisors. Known as the Riverside County Projections 2010 (RCP-10) these data are also used throughout this EIR, including in the projections of this section, where indicated. Further, these same projections are built into the RIVTAM traffic modeling performed for this project, EIR and alternatives, and were also submitted to SCAG for their use in developing the 2012 RTP, among other plans. See Section 5.6 (Regional Consistency) for a full discussion of regional plans.

A. No Build / No Growth Alternative

As stated in Section 15126.6(e) of the State CEQA Guidelines, "the purpose of describing and analyzing a no project alternative is to allow decision-makers to compare the impacts of approving [or not approving] the proposed project." The section further states, "the 'no project' alternative shall discuss the existing conditions...as well as what would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with the available infrastructure and community services."

Subsection 3 of these same Guidelines specifies that there are "two lines" of analysis for addressing no project alternatives. In the first, the no project alternative assumes the "continuation of the existing plan." The second includes a "No Build" scenario, "wherein the existing environmental setting is maintained." This second no project scenario is covered by the No Build/No Growth alternative discussed here. The other is addressed as the No Project/Status Quo alternative presented after this one.

Although the No Build alternative does include some "artificial assumptions" in order to "preserve the physical environment," it is nonetheless included among the alternatives considered because of its utility in providing a clear examination of the effects of future growth in the cities within Riverside County, as well as the surrounding cities and counties. It also serves to paint a clear picture of how these areas' growth will themselves affect the unincorporated portions of Riverside County, even in the absence of any other unincorporated growth. Though an admittedly extreme example, as explained above, this alternative provides a means for distinguishing the specific effects of unincorporated county growth (either as accommodated by the proposed project or as projected by one of the other alternatives) from that of the cities and surrounding jurisdictions.

1. Assumptions

For this alternative, it is assumed that the updates to the General Plan proposed under GPA No. 960 would not be adopted and no further building would occur within the unincorporated portions of Riverside County. This prohibition would compel any subsequent development to occur in the incorporated cities of the county, or in the surrounding cities and counties, shifting any regional incremental growth in population, housing or employment to those areas.

a. Additional Assumptions

The No Build alternative includes the following assumptions as part of its project description:

- No new development is approved within the unincorporated portions of Riverside County. The incorporated cities within Riverside County, however, do continue to grow and build out pursuant to their individual General Plans. In order to maintain consistency among the various alternatives, no future annexations of unincorporated lands into the various cities are included. It is also assumed no development would occur within the cities' spheres of influence since such areas would remain part of unincorporated Riverside County.

- The only growth or development assumed to occur within unincorporated Riverside County is that constructed to provide new infrastructure or improve existing infrastructure capacity, as necessary to serve the growing cities. This refers particularly to improvements to roadways, water conveyance and sewer treatment facilities, and regional flood control; that is, mainly regional projects.

- GPA No. 960 (the proposed project) would not be approved. The technical and regulatory updates needed for the General Plan (e.g., statistical updates, resource mapping revisions, regulatory changes, etc.) are, however, adopted. None of the changes alters the General Plan's existing land use policies and maps in terms of planned densities or intensities, however. Thus, no LUD changes are made, no Rural Village Study Areas are updated or deleted, no new Rural Village Overlays are created and so on.

- The County of Riverside would not provide any additional housing to meet Regional Housing Needs Assessment (RHNA) targets as assigned by SCAG.

- Although the General Plan would be updated to discuss climate change and greenhouse gas regulation, the current draft CAP included with GPA No. 960, is assumed to not be adopted and implemented. Specifically, because this alternative poses no new development within unincorporated Riverside County, the existing draft CAP could not be implemented (as it focuses mainly on future new development).

- Implementation of the Western Riverside (WR) MSHCP and the Coachella Valley MSHCP (CV-MSHCP) are assumed to continue, but only through the participating cities in Riverside County. With no development occurring in the unincorporated areas, no associated funding for habitat acquisition would be generated from county sources. However, the existing open space within unincorporated Riverside County would also be left largely undisturbed and as such the acquisition of additional conservation lands would generally not be needed as compensation.

- With no new development occurring in unincorporated Riverside County, no County DIF (development impact fees) or Transportation Uniform Mitigation Fee (TUMF) program funds would be generated from this source. The TUMF program imposes fees on development to address transportation impacts on local arteries, specifically the funds are used to make selected transportation improvement projects along the adopted TUMF arterial network. Absent county growth, it is assumed that TUMF network improvements within Riverside County would be revised to prioritize circulation network improvements based chiefly on needs within the (growing) cities and secondarily on county roads conveying city-generated cross-traffic.

- It is assumed that the circulation networks within the cities of Riverside County, as well as those of the surrounding cities and counties would generally be improved as planned for by the cities' existing General Plans and regionally as planned for by SCAG's 2012 RTP (to the extent still applicable) to coordinate regional circulation its cities and counties as well. Within the unincorporated portions of Riverside County, it is assumed that, with a few noted exceptions, no future roadway improvements would occur, existing roadways would generally remain in their current state and the countywide circulation network plan portrayed in the existing General Plan (Figure C-1) would not be realized.

- The exceptions to this lack of traffic improvements would be where regional and, in particular, city traffic triggers the need for roadway improvements within unincorporated Riverside County and sufficient funds are generated by the cities and other existing revenue streams (for example Measure A funds) to pay for such improvements. Similarly, it is assumed that the State of California (Caltrans) and federal agencies would continue to perform certain improvements to the state and federal highways passing through unincorporated Riverside County. However, such improvements would be limited to those needed to address the traffic increases arising from the growth in the cities and surrounding counties. The unincorporated areas would not contribute to the increasing traffic on these systems.

b. Baseline Assumptions

As with all of the other alternatives, as well as the rest of the EIR for that matter, the starting baseline assumptions for the No Build alternative are the existing physical conditions within Riverside County. Full details on these existing conditions are provided throughout the EIR and, in particular, conditions for each environmental issue are presented in the section addressing that topic. For example, Section 4.5 (Agricultural and Forestry Resources) provides information on existing mapped farmlands, existing forestry resources, etc., within Riverside County. This baseline condition applies to both the incorporated and unincorporated portions of Riverside County. See Table 6.4-A (No Build/No Growth Alternative – Assumptions and Projections) for the full baseline data set used for this alternative. See the footnotes to this table for additional comments on the baseline assumptions.

c. Build Out Assumptions

For this particular alternative, it is assumed that no new development is approved within the unincorporated portions of Riverside County. As such, the build out assumptions for this part of the county and region are proposed to remain the same as that of the baseline conditions outlined above.

For the cities within Riverside County, however, growth is assumed to occur as directed by each city's individual General Plan, subject to the criteria previously noted above. Thus, the build out conditions for this alternative use the baseline assumptions unchanged for the unincorporated portion of Riverside County, but built-out (developed) conditions are applied to the incorporated cities. See Table 6.4-A for the full build out data set used for this alternative. See the footnotes to this table for additional comments on the build out assumptions.

2. Environmental Implications

Section 15126.6(d) of the State CEQA Guidelines notes that, "A matrix displaying the major characteristics and significant environmental effects of each alternative may be used to summarize the comparison. If an alternative would cause one or more significant effects in addition to those that would be caused by the project as proposed, the significant effects of the alternative shall be discussed, but in less detail than [those] of the project as proposed."

Table 6.4-A: No Build / No Growth Alternative – Assumptions and Projections

No Build / No Growth Alternative ASSUMPTIONS [5]	Baseline: Existing (2007) Conditions[1, 2]			Build Out: Future (2060) Conditions[1,2 4]

Footnotes:

1. Source for land use, existing and build out: EIR Table 4.2-F for all except, "Cities, Build Out," which were estimated from RCCDR 2012 data.
2. Source for socioeconomic data: EIR Table 4.3-G.
3. Since their incorporations occurred after the date of NOP issuance for this EIR, the cities of Eastvale and Jurupa Valley are generally included in the unincorporated Riverside County totals, rather than the incorporated totals for baseline conditions. Category totals estimated from proportional growth projections.
4. Build out conditions are those projected at full realization of the alternative's land use plans. For this alternative, the build out scenario includes the following assumptions:
   a. No new development occurs in the unincorporated portion of Riverside County (that is, build out values equal the baseline values). Also, no additional unincorporated lands are annexed into any cities.
   b. The incorporated portions of Riverside County fully develop (build out) according to the land uses mapped in the existing General Plans for the individual cities (as interpreted by RCCDR).
   c. The cities of Eastvale and Jurupa Valley are generally included in the incorporated build out totals.
5. All values rounded to the nearest hundred. Thus, totals may not sum precisely.
6. Commercial uses include commercial-retail, commercial-office, commercial-tourist, community center and MUPA (mixed-use).
7. Industrial uses include heavy and light industry, business parks, warehouses and public facilities, as well as mining and (active) recreational uses.
8. Open space uses include conservation lands, as well as water (lakes, reservoirs, etc.).

9. "Other" uses encompass any not listed elsewhere and include freeways, roads, canals, etc., as well as vacant (undeveloped) lands.
Source: See footnotes, above, for data sources.

With this in mind, in addition to the basic land use and socioeconomic data presented above, a second table was created to briefly indicate the environmental effects projected for the given alternative. As per the above directive, where significant items arise, they are discussed further below.

For this alternative, with no additional development occurring in unincorporated Riverside County, most of the environmental impacts within Riverside County would be substantially less adverse than those of the proposed project. In a few areas, such as certain air quality impacts, seismic risks, noise exposure, traffic levels and stormwater drainage needs, existing (baseline) environmental effects are already at a significant level and the alternative would not relieve or lessen these impacts.

As shown in Table 6.4-B (No Build/No Growth Alternative – Environmental Effects Summary), this alternative would have a number of significant environmental effects (either individual, in localized areas or cumulative). Certain of these significant environmental effects would be substantially worse than those associated with the project-updated General Plan. These effects, which are discussed further below, include:

- Greenhouse gas emissions and conflicts with regulatory compliance.
- Inefficient use of energy.
- Circulation system effectiveness and congestion management conflicts.
- Increased traffic levels in localized areas.
- Groundwater depletion or overdraft.
- Population increase straining community services or facilities.
- Facilitation of other activities leading to significant environmental effects (in particular, increasing the rate of growth within the cities of Riverside County and surrounding cities and counties; see discussion, below).

a. General Impacts

As indicated in Table 6.4-B, the No Build/No Project Alternative would have predominantly fewer adverse environmental effects within unincorporated Riverside County than would the proposed project. This is due mainly to the elimination of future development within unincorporated Riverside County under this alternative. With no new development occurring, no additional impacts would occur to existing resources, such as wetlands, viewsheds, minerals and so on. In addition, the lack of development would also mean that the population of unincorporated Riverside County would not increase. As such, there would be no increased demand on existing facilities, such as schools, wastewater treatment facilities, etc., serving unincorporated areas.

b. Agriculture

Although state-designated farmlands within cities would not be protected from conversion, the bulk of Riverside County's farmlands (75%) are located in the outlying unincorporated portions of the county. With no growth in

unincorporated Riverside County, there would also be no additional loss of designated farmlands in these areas. For this reason, this alternative's farmland impacts would generally be less than the project's.

Table 6.4-B: No Build / No Growth Alternative – Environmental Effects Summary

Impact #	Impact Title / Description [1, 6]	No Impact	Less Than Signif.[2]	Less Than Signif. With Mitigation[2]	Significant [3]	Cumul. Significant	Relative to Proj.[4]	Effects on Cities [5]
4.2 – Land Use								
4.2.A	Physically divide an established community.		•				↓	LTS
4.2.B	Conflict with land use policies intended to avoid or mitigate an environmental effect.		•				↓	LTS
4.2.C	Conflict with any habitat conservation plan or natural community conservation plan.		•				↓	LTS
4.3 – Population and Housing								
4.3.A	Induce direct or indirect population growth.		•				↓	SIG
4.3.B	Displace residential units.		•				↓	LTS
4.3.C	Displace people.		•				↓	LTS
4.4 – Aesthetic and Visual Resources								
4.4.A	Adversely affect scenic vistas.		•				↓	LTS-M
4.4.B	Adversely affect scenic resources within State Scenic Highways.		•				↓	LTS-M
4.4.C	Adversely affect existing visual character.		•				↓	LTS-M
4.4.D	Cause adverse light and glare effects.		•				↓	LTS-M
4.4.E	Interfere with nighttime use of the Palomar Astronomical Observatory.		•				↓	LTS-M
4.5 – Agricultural and Forestry Resources								
4.5.A	Cause direct or indirect conversion of designated Farmlands.		•				↓	LTS-M
4.5.B	Encroach on or conflict with existing agricultural uses.		•				↓	LTS-M
4.5.C	Adversely affect forest lands and forestry uses.		•				↓	LTS
4.6 – Air Quality								
4.6.A	Conflict with air quality plans.		•				↓	LTS-M
4.6.B (1)	Cause significant construction (short-term) air emissions.			•			↓	SIG
4.6.B (2)	Cause significant operational (long-term) air emissions.				•	•	↓	SIG
4.6.C	Cause cumulatively significant project air quality impacts.			•			↓	SIG
4.6.D	Expose sensitive receptors to air pollutants.				•	•	↓	SIG
4.6.E	Expose substantial numbers of people to objectionable odors.		•				↓	LTS
4.7 – Greenhouse Gases								
4.7.A	Generate substantial greenhouse gas emissions.						↓↑	LTS-M
4.7.B	Conflict with greenhouse gas reduction plans, policies or regulations.						↑	LTS-M
4.8 – Biological Resources								
4.8.A	Adversely affect riparian or other sensitive habitats.		•				↓	LTS-M
4.8.B	Cause direct and indirect impacts to protected species or their habitats.		•				↓	LTS-M
4.8.C	Adversely affect wetlands.		•				↓	LTS-M
4.8.D	Impede species movement, migration, wildlife corridors or use of wildlife nursery sites.		•				↓	LTS-M
4.8.E	Conflict with adopted habitat conservation plans.		•				↓	LTS-M

Impact #	Impact Title / Description [1, 6]	No Impact	Less Than Signif.[2]	Less Than Signif. With Mitigation[2]	Significant [3]	Cumul. Significant	Relative to Proj.[4]	Effects on Cities [5]
4.8.F	Conflict with local biological resource protection policies or ordinances.		•				↓	LTS-M
4.9 – Cultural and Paleontological Resources								
4.9.A	Adversely change the significance of historical resources.		•				↓	LTS-M
4.9.B	Cause the destruction of known archeological resources.		•				↓	LTS-M
4.9.C	Cause destruction of unique paleontological resource or site.		•				↓	LTS-M
4.9.D	Result in the disturbance of human remains.		•				↓	LTS-M
4.10 – Energy Resources								
4.10.A	Increase demand for electricity.		•				↓	LTS-M
4.10.B	Increase demand for natural gas.		•				↓	LTS-M
4.10.C	Cause the inefficient use of energy.						↑	LTS
4.11 – Flood and Dam Inundation Hazards								
4.11.A	Result in housing within flood hazard areas.		•				↓	LTS-M
4.11.B	Cause impediment of flows.		•				↓	LTS-M
4.11.C	Expose people or structures to flooding hazards, including flooding due to dam or levee failure.		•				↓	LTS-M
4.11.D	Cause the adverse alteration of drainage patterns or substantially increase surface runoff.		•				↓	LTS-M
4.11.E	Cause inundation risks due to seiche, tsunami or mudflow.		•				↓	LTS-M
4.12 – Geology and Soils								
4.12.A	Expose people or structures to substantial adverse effects due to rupture or a known earthquake fault.		•				↓	LTS-M
4.12.B	Expose people or structures to substantial strong seismic groundshaking.		•			•	↓	SIG
4.12.C	Expose people or structures to substantial adverse effects due to seismic-related ground failure, including liquefaction.		•				↓	SIG
4.12.D	Expose people or structures to substantial adverse effects due to landslides.		•			•	↓	SIG
4.12.E	Result in substantial soil erosion or topsoil loss.		•				↓	LTS-M
4.12.F	Result in development on unstable geological units or soils.		•				↓	LTS-M
4.12.G	Result in development on expansive soil.		•				↓	LTS-M
4.12.H	Result in development on soils incapable of supporting septic tanks or alternative wastewater disposal systems.		•				↓	LTS-M
4.13 – Hazardous Materials and Safety								
4.13.A	Create a significant hazard through the routine transport, use or disposal of hazardous materials.		•				↓	LTS
4.13.B	Cause a significant hazard through the accidental release of hazardous materials.		•				↓	LTS
4.13.C	Result in hazardous emissions or related hazards within ¼-mile of a school.		•				↓	LTS
4.13.D	Result in a significant hazard due to development on a Cortese List hazardous materials site.		•				↓	LTS
4.13.E	Result in a safety hazard for people within a two-mile radius of a public or public use airport.		•				↓	LTS
4.13.F	Result in a safety hazard for people in the vicinity of a private airstrip or heliport.		•				↓	LTS
4.13.G	Impair or interfere with adopted emergency response or evacuation plans.		•				↓	LTS

Impact #	Impact Title / Description [1, 6]	No Impact	Less Than Signif.[2]	Less Than Signif. With Mitigation[2]	Significant [3]	Cumul. Significant	Relative to Proj.[4]	Effects on Cities [5]
4.13.H	Expose people or structures to significant risk due to wildland fire.		•				↓	LTS
4.14 – Mineral Resources								
4.14.A	Result in the loss of availability of delineated locally important minerals.	•					↓	LTS
4.14.B	Result in the loss of availability of known mineral resources.		•				↓	LTS-M
4.15 – Noise								
4.15.A	Generate noise or cause noise exposure in excess of standards.				•	•	↓	SIG
4.15.B	Generate or cause exposure to excessive groundborne vibration.			•			↓	LTS-M
4.15.C	Result in a substantial permanent increase in ambient noise.		•				↓	SIG
4.15.D	Result in a substantial temporary or periodic increase in ambient noise.			•			↓	SIG
4.15.E	Expose people to excessive airport-related noise levels.		•				↓	LTS
4.16 – Parks and Recreation								
4.16.A	Increase the use of existing parks or recreational facilities resulting in their substantial physical deterioration.		•				↓	LTS-M
4.16.B	Trigger growth effects resulting in the need for additional parks or recreational facilities.		•				↓	LTS-M
4.16.C	Result in significant adverse effects due to the need for additional parks or recreational facilities.		•				↓	LTS-M
4.17 – Public Facilities								
4.17.A	Cause adverse environmental effects due to the need for fire protection services.		•				↓	LTS-M
4.17.B	Cause adverse environmental effects due to the need for law enforcement services.		•				↓	LTS-M
4.17.C (1)	Adversely affect or exceed the permitted capacity of a landfill.		•				↓	LTS-M
4.17.C (2)	Cause inconsistencies with applicable statutes and regulations related to solid waste, including the County Integrated Waste Management Plan.		•				↓	LTS
4.17.D	Cause adverse environmental effects due to the need for schools.		•				↓	SIG
4.17.E	Cause adverse environmental effects due to the need for library services.		•				↓	SIG
4.17.F	Cause adverse environmental effects due to the need for medical facilities.		•				↓	LTS
4.18 – Transportation and Circulation								
4.18.A	Conflict with circulation system effectiveness regulations for any transportation, including vehicular, mass transit and non-motorized travel.						↓↑	SIG
4.18.B	Conflict with a congestion management program, including level of service (LOS) standards and travel demand measures.				◊		↓↑	SIG
4.18.C	Cause substantial safety risks as a result of a change in air traffic patterns.		•				↓	LTS
4.18.D	Cause substantial alterations in waterborne, rail or air traffic.		•				↓	LTS
4.18.E	Substantially increase road hazards due to design or incompatible uses.		•				↓	LTS
4.18.F	Cause an adverse effect on or need for new or altered road maintenance.		•				↓	LTS
4.18.G	Cause an adverse effect on circulation during construction.		•				↓	LTS
4.18.H	Result in inadequate emergency access.		•				↓	LTS
4.18.I	Conflict with policies for public transit or non-motorized travel, or decrease the performance or safety of such facilities.		•				↓	LTS
4.19 – Water Resources								
4.19.A	Result in insufficient water supply.		•				↓	SIG

Impact #	Impact Title / Description [1, 6]	No Impact	Less Than Signif.[2]	Less Than Signif. With Mitigation[2]	Significant [3]	Cumul. Significant	Relative to Proj.[4]	Effects on Cities [5]
4.19.B	Substantially deplete groundwater supplies or substantially interfere with groundwater recharge.		•			◊	↑	LTS-M
4.19.C	Substantially degrade water quality.		•				↓	LTS-M
4.19.D	Violate water quality standards or waste discharge requirements.		•				↓	LTS-M
4.19.E	Exceed wastewater treatment requirements.		•				↓	LTS-M
4.19.F	Exceed wastewater treatment capacity.		•				↓	LTS-M
4.19.G	Result in significant adverse effects due to the construction of new or expanded water or wastewater facilities.		•				↓	LTS-M
4.19.H	Substantially alter existing drainage patterns resulting in substantial erosion or siltation.		•				↓	LTS-M
4.19.I	Cause runoff exceeding stormwater drainage system capacities or cause substantial water pollution.		•				↓	LTS-M
4.19.J	Cause significant adverse effects due to the need for new or expanded stormwater drainage facilities.		•			•	↓	LTS-M
5.2 – Significant Irreversible Changes								
5.2.A	Result in a large commitment of non-renewable resources that make later removal or non-use unlikely.		•				↓	SIG
5.2.B	Result in the unjustified commitment of irretrievable resources.		•				↓	LTS
5.2.C	Result in primary or secondary impacts that generally commit future generations to similar uses.		•				↓	SIG
5.2.D	Result in an environmental accident that could cause irreversible damage.		•				↓	LTS
5.4 – Significant Growth-Inducing Effects								
5.4.A	Foster direct or indirect economic growth.		•				↑	SIG
5.4.B	Foster direct or indirect population growth.		•				↑	SIG
5.4.C	Result in construction of additional housing.		•				↓	SIG
5.4.D	Remove obstacles to population growth.		•				↓	LTS
5.4.E	Facilitate other activities leading to significant environmental effects; e.g., encroach into isolated or remote areas.				•		↑	SIG
5.4.F	Result in population increase that may strain community services or facilities.				•		↑	SIG

Footnotes:

1. Impacts are based on a comparison of the effects of build out of the alternative as compared to the environmental baseline. Unless noted otherwise in the text, the environmental baseline is assumed to be the same as or substantially similar to that described for the proposed project in Sections 4.0 through 5.0 of the EIR.
2. Only impacts requiring new CEQA-specific mitigation measures to reduce their impacts to less than significant are considered to be "less than significant with mitigation." (Compliance with existing laws, ordinances, regulations, etc., is assumed under CEQA.)
3. Diamond (◊) denotes an impact that is substantially greater than for the General Plan as updated per GPA No. 960.
4. Severity of projected impacts relative to proposed project (rather than environmental baseline), for comparison purposes: ↓, less severe; ↑, more severe; ↓↑ = areas of each result; and, = , approximately the same.
5. Summary of overall effects on cities within Riverside County. LTS = less than significant; LTS-M = less than significant with mitigation; SIG = significant. See text for discussion of these results.
6. Shaded yellow boxes denote impact finding for build out of the General Plan with GPA No. 960 (per Table 5.5-AJ) for comparison.

Source: Riverside County Planning Dept., new analysis and results from EIR Sections 4.2 - 4.19 and 5.1 - 5.5, 2012.

c. Traffic and Circulation Impacts

In terms of traffic, there would be no population-triggered increase in vehicle miles traveled (VMT) or associated increases in air pollutant emissions, greenhouse gas emissions, odors, ambient noise levels, etc. As such, the

project would have substantially fewer future impacts in these areas. However, without growth in Riverside County, the network of roads proposed in the Riverside County General Plan (General Plan Figure C-1) also would not be realized. The only circulation improvements within unincorporated Riverside County would be those made by the state and federal governments to the freeways and highways under their jurisdictions. There may also be regional (RCTC) improvements where there is sufficient city-generated funding for their construction within unincorporated Riverside County.

Thus, within unincorporated Riverside County, existing roadway segments or intersections currently at unacceptable levels of service generally would remain as such. Further, as development progresses within adjacent cities, Riverside County roadways used for transport to and from these cities would see increasing levels of traffic and congestion. It is for these reasons that Impacts 4.18.A and 4.18.B for the No Build/ No Growth Alternative would both be significant and unavoidable, as well as cumulatively significant. All other areas of traffic-related impacts for the alternative would be less than significant since unincorporated Riverside County's population would not be increasing.

d. Air Quality, Greenhouse Gas and Energy Impacts

In terms of air quality, this alternative would have substantially fewer future impacts since no development would be occurring in the unincorporated portions of Riverside County. Also, with no new development, there would be no population-triggered increase in VMT in these areas. Since vehicle travel directly affects noise levels and the emissions of pollutants and greenhouse gases, future increases in these areas would not occur under this alternative.

Likewise, with so little development occurring within unincorporated Riverside County, under this alternative it was determined that short-term (construction-related) air emissions would be less than significant both individually as well as cumulatively (since what construction did occur in the county would be spaced further apart and thus less likely to cause a cumulatively significant impact on any single given day).

Where existing (baseline) conditions are already significant, such as operational emissions of certain air pollutants (e.g., O_3, PM_{10} and $PM_{2.5}$ in both the South Coast and Mojave Desert Air Basins), the alternative's effects would remain significant since it would not reduce such emissions. This is particularly true for greenhouse gas emissions which would not be reduced in the absence of Riverside County implementation of the proposed CAP. As such, the County of Riverside would not need to mitigate the effects of new development (that is, further reduce GHG emissions by 15%).

However, there also would be no plan for Riverside County to address energy conservation within existing homes and businesses as the CAP addresses energy conservation (i.e., decreasing electricity and natural gas usage) as a means for decreasing GHG emissions. Under this alternative, there would be no implementation of policies to improve energy efficiency in existing homes and businesses. Thus, particularly for structures built prior to introduction of California State's Title 24 energy conservation codes, energy-inefficient uses would remain unrelieved under this alternative. Thus, Impact 4.10.C was deemed significant for this alternative.

Absent a CAP, this alternative would result in a new significant impact related to inconsistency with California State's AB 32 GHG reduction goals. The CAP proposed in conjunction with GPA No. 960 primarily addresses GHG emissions from new development. As such, absent the new development measures, the plan would not achieve the necessary reductions from existing uses needed to reduce existing emissions by an additional 15%, as called for by the State of California. As shown in Table 4.7-F in Section 4.7 (Greenhouse Gases), the baseline (2008) greenhouse gas emissions totaled 7.102 million metric tons of carbon dioxide equivalents (CO_2e). To be compliant with AB 32, the County of Riverside would need to reduce this to 6.037 million metric tons, even with

no additional future development or growth in Riverside County. Since existing emissions would remain substantial and would not be reduced by the County of Riverside, this alternative would have significant effects under both Impacts 4.7.A and 4.7.B.

e. Noise Impacts

As with air quality, for noise impacts this alternative would have substantially fewer future impacts since no development would be occurring in the unincorporated portions of Riverside County. Also, with no new development, there would be no population-triggered increase in VMT in these areas. Since motor vehicle travel is the largest single source of noise generation in Riverside County and directly affects noise levels for receptors along roadways, future increases in ambient noise levels, as well as construction noise levels, would not occur under this alternative.

Likewise, with so little development occurring within unincorporated Riverside County, under this alternative most of the cumulative effects of noise would also be less than significant. The exception being that this alternative would result in cumulatively significant noise levels along county roads that would see an increase in traffic due to growth within the cities. Similarly, where county roads generate existing levels of noise in excess of standards, these future traffic increases would result in localized, as well as cumulatively significant, noise exposures.

f. Geology and Soils Impacts

As with many other spatial impacts, in terms of geology and soils, the No Build / No Project Alternative would have predominantly fewer adverse environmental effects within unincorporated Riverside County than would the proposed project because of the lack of future development in the county. Since this would also mean the population of unincorporated Riverside County would not increase, future risks to additional people and properties due to development in areas prone to seismic and other geologic hazards would not occur. However, even without additional development, much of Southern California, including much of Riverside County, is subject to strong seismic groundshaking risks. As such, this impact (4.12.B) would remain cumulatively significant for this alternative even without future development. For similar reasons, the cumulative risk to people and structures due to landslide and rockfall hazards (Impact 4.12.D) would also remain significant under this alternative.

g. Water Impacts

The lack of future development associated with this alternative would mean that additional demands on future water supplies would be limited. In general, this means that additional potable water supplies and the infrastructure to treat and deliver such water would not be needed within unincorporated Riverside County beyond already identified existing needs. And, since water infrastructure is funded by the water utility's customers, it may be safely assumed that future infrastructure needs, particularly for imported water supplies, would be able to be adequately met through existing funding and implementation mechanisms. Such measures would also adequately address the needs for wastewater conveyance, treatment and disposal.

Thus, overall, this alternative would have substantially fewer adverse effects on water resources. However, there are two exceptions to this conclusion: First, as with the proposed project, this alternative would have a significant adverse effect on the environment due to the need for new stormwater drainage facilities as portions of unincorporated Riverside County currently experience insufficient stormwater drainage. In some of these areas, without the funds generated by future development, it is likely that necessary stormdrain facilities would not be constructed. The result would be cumulatively significant adverse effects on existing lands due to inadequate stormwater controls (Impact 4.19.J).

Second, this alternative would also result in significant adverse effects to groundwater supplies, possibly even causing overdraft, in portions of Riverside County relying solely on groundwater basins for their potable water supplies. In areas where water is supplied through individual wells, particularly some of the more rural portions of the unincorporated county, the lack of a water district to organize and fund water infrastructure improvements would mean that groundwater remained the sole water source. Thus, lack of future imported water availability would result in a cumulatively significant impact (i.e., Impact 4.19.B) where a water basin is already in overdraft or where the current basin withdrawals exceed its replenishment (which would eventually lead to depletion of the basin).

h. Growth Inducement and Impacts to Cities

As clearly outlined above, by restricting growth and development within unincorporated Riverside County, the No Build/No Growth Alternative would result in no increase in population and little to no increase in Riverside County's existing development footprint. Within the cities of Riverside County, however, a different pattern would result. These locales would bear the brunt of future development demand. A large portion of the population seeking residency within the Inland Empire would be have no choice other than Riverside County's cities or surrounding cities and counties.

Under this alternative, it was assumed that growth within the cities would occur in accordance with each city's general plan, as required by state law. This would hold true even in the face of increased growth pressure from the unincorporated areas. See Table 6.4-A for RCCDR estimated build out results for incorporated Riverside County. The principle difference brought about by this alternative would be that the *rate* of the anticipated growth in the cities would be accelerated compared to that currently expected and planned for by the cities' general plans. For impacts to cities listed as "less than significant with mitigation" in Table 6.4-B, it is assumed that existing regulatory compliance and, where necessary, compliance with city-specific CEQA mitigation measures, would be sufficient to ensure the impact is less than significant. For these impacts, the feasibility of successful mitigation to less-than-significant levels was based on examples in the EIR for the Riverside County General Plan or various specific city general plans in which such findings were made.

Given the assumption that cities would build out according to their existing general plans, despite the increased growth pressure (and thus growth rate) experienced, this alternative would result in a number of significant adverse environmental effects within the cities as a result. These include:

- The cities would experience significant direct and indirect population growth. They would also experience a significant increase in the rate of direct and indirect population growth.

- The cities would continue to experience significant short-term and long-term air pollutant emissions, as well as cumulatively significant air emission increases. The increased rate of development within the cities would mean that short-term construction impacts on air quality are more likely to be cumulatively significant since more projects would be developing at the same time, collectively exceeding thresholds set by SCAQMD.

- With growth concentrated in cities instead of spread out across Riverside County, existing and future city residents would be subject to increased local pollutant concentrations.

- The cities would experience significant short-term air pollutant emissions as vehicle trips increase more rapidly than planned, outpacing the pollution-lowering effects of the various state regulations (e.g., improved fuels, increased engine efficiency requirements, etc.) being implemented between now and 2020 (and beyond) pursuant to AB 32 and CARB's AB 32 Scoping Plan. Also, more homes would be built

under existing California State Title 24 (energy efficiency) requirements. Since the State of California has been tightening Title 24 requirements every two years, such homes would have been required to meet higher standards if developed two or more years later.

- As with any development within Southern California, where cities are located within regions mapped with the potential for strong seismic groundshaking in the event of a major earthquake, there would be a cumulatively significant risk for the exposure of people and structures to strong groundshaking. (This risk, however, would be no different than for the rest of Riverside County.)

- Where development within cities would occur in areas with landslide or rockfall potential, there would be a cumulatively significant risk for the exposure of people and structures to landslide or rockfall hazards.

- Where existing noise levels already exceed acceptable noise standards, additional development within the cities would further exacerbate such significant noise impacts. Additional development would also increase noise levels in some locations from currently acceptable to unacceptable noise levels. This would be particularly likely for residential areas adjacent to city and county roadways with existing or future unacceptable traffic volumes that would not be planned for roadway improvements under this alternative. Increased development within cities would also expose more people (existing and future) to potentially significant short-term construction impacts. As traffic volumes increase in the cities, existing sensitive receptors (residents, school children, hospital patients, etc.) would more quickly be exposed to noise levels in excessive of the standards. The increased rate of development within the cities means that short-term construction impacts are more likely to be cumulatively significant since more projects would be developing at the same time.

- This alternative would significantly affect schools because it would selectively increase the concentrations of students in the school districts serving incorporated areas. In addition to selectively increasing the concentrations of students in the school districts serving incorporated areas, this alternative would also increase the rate at which new schools and related facilities would be needed within the cities.

- This alternative would have significant adverse effects on city libraries because it would selectively increase the concentrations of library patrons within the cities, as opposed to the unincorporated portions of Riverside County. In addition to selectively increasing the adverse effects on city libraries, this alternative would also increase the rate at which new libraries, books and related facilities would be needed within the cities to serve their growing number of library patrons.

- Growth occurring within cities would result in increased vehicle trips within both the cities and the county for trips to and from the cities. With little to no additional county roads built under this alternative, the increased traffic would lead to significant unavoidable impacts within both the cities and within portions of Riverside County serving as links to/from the cities. Significant traffic impacts would arise on the individual and cumulative levels for circulation system effectiveness and for congestion management within both the cities and Riverside County. Surrounding cities and counties, particularly those adjacent to Riverside County, would likely be similarly affected.

- The increased growth rate within cities would result in roadways more rapidly reaching unacceptable traffic levels in various locations within both the cities and the county. Further, even where future plans would alleviate traffic congestion, the increased rate of development in the cities could in some cases result in a longer wait for the necessary improvements to be constructed. This may particularly be true of state (Caltrans) or federal (FHWA) projects in which priorities must balance statewide or national needs, rather than focusing solely those of the local populace.

- Cities are generally planned so that build out of their general plans would not exceed their available water supplies. Under this alternative, however, it is possible that the rate of a city's growth could outpace the ability of existing and/or planned water supplies to meet the resultant need. In particular, where a city relies upon groundwater, if the increased demand exceeds the basin's recharge capacity (or the water provider's plans to increase said capacity), overdraft of the groundwater basin could result in a significant impact.

- By definition, development within the cities would result in a significant commitment of nonrenewable resources that would make its later removal or non-use unlikely.

- Development within the cities would result in primary and secondary impacts that would generally commit future generations to similar uses.

Lastly, it is possible that under this alternative increased growth pressure in the cities could lead to increased development above that currently planned. At present, the cities of Riverside County are projected to provide a total of approximately 1.04 million dwelling units at build out (83% of the countywide total) with unincorporated Riverside County only providing roughly 207,000 more units. This would leave a housing deficit of over 520,000 homes within the unincorporated areas under this alternative. Notwithstanding the existing cities' general plans, making up this half-million-plus deficit within the cities would require significant changes in city general plans and result in a number of additional significant impacts within the cities.

The cities would need to increase their housing densities to accommodate the additional expected population (of 1.15 million people overall). They would also need to add enough additional economic uses (commercial, industrial, agricultural, etc.) to provide an additional 454,000 jobs within the cities. The increased number of people and employees present within the cities would significantly increase the amount of traffic, noise and air pollution within the cities because the same amount of effects that would have been spread over the entire county (roughly 4,011,000 acres excluding tribal, state and federal lands) would instead be spread over the roughly 542,000 acres encompassed by cities. As a result, the following new significant environmental impacts would occur in the cities of Riverside:

- Increased densities would lead to increased direct and indirect population growth. These impacts would be significant because they would exceed the totals currently planned in the cities' existing general plans. This alternative's impact would exceed that of the proposed project (i.e., build out of the Riverside County General Plan pursuant to the changes proposed by GPA No. 960).

- Increased development would increase the number of vehicle trips occurring within the cities, as well as those entering and leaving the cities. The traffic studies were performed for this project and a variety of scenarios, including the cities-only scenario described by this alternative; see tables in Section 4.18 and in EIR Appendix EIR-4 (Traffic Study).

- The higher densities within the cities would contribute, in large part, to the increased traffic seen in the county. This increased traffic would result in increased emissions where traffic congestion leads to longer commute times over the same distances. However, as a side effect of increased development in the cities, local commutes would also be shorter for many (resulting in VMT reductions) due to the availability of jobs, shopping and other destinations locally. Overall, however, the increased density overshadows any VMT reductions and the overall cumulative impact of this alternative on the cities would ultimately be significant and unavoidable.

- The increased development would result in significant increases of air pollutant emissions, both long- and short-term, in localized areas (i.e., concentrated in cities, rather than spread across the whole county). This would also result in the exposure of a significant number of sensitive receptors (children, elderly, the infirm, etc.) to air pollutants in these localized areas. The higher densities within the cities would contribute, in part, to reduced pollution due to lower vehicle miles traveled (as opposed to whole-county build out). However, these reductions would in part be offset by increased emissions where traffic congestion leads to longer commute times over the same distances. Overall, however, the increased density overshadows the VMT reductions and the overall cumulative impact of this alternative on the cities would be significant and unavoidable.

- The increased development would result in significant increases vehicle trips within localized areas (i.e., concentrated in the cities, rather than spread across the whole county). As a result, noise levels would increase in excess of standards in more areas within the cities than would have occurred under this project (with trips spread out countywide). This could also include cause additional portions of the cities that otherwise would have remained under acceptable thresholds to exceed noise limits. Thus, this alternative could result in significant new noise impacts within the cities due to additional noise generation and could also cause substantial permanent increases in ambient noise levels in the cities.

- Under this alternative, increased densities would lead to increased population growth that exceeds that currently planned in the cities' existing general plans. As such, this alternative could cause the substantial deterioration of existing recreational facilities within the cities serving populations that would have otherwise been spread across the county instead.

- The population increases in the cities from this alternative would also trigger the need for additional recreational, schools, governmental, health, library, law enforcement, fire services and other public services and facilities. The land necessary to provide these uses would be acquired from existing vacant land, agricultural land, open space (conservation or recreational lands) or land already planned (or built) to serve other uses (rural residential, for example). As such, it would be increasingly likely that the construction of such necessary services and infrastructure improvements would result in additional adverse environmental impacts. Since similar types of development within the unincorporated portions of Riverside County could be more easily accommodated in a manner that avoids significant effects to the physical environment (chiefly due to the greater inventory of vacant land to select from), the effects of this alternative on the environment due to the need to provide additional utilities, infrastructure, public facilities and services would likely be substantially greater than that of the proposed project. These impacts would also result in significant growth-induced strain on community services and facilities in the cities.

- The increased economic and population growth fostered within the cities by this alternative would result in significant growth-inducing effects. Because these growth effects would exceed the levels planned for in the individual city general plans, this alternative would have a greater effect on the cities than the proposed project would on the surrounding unincorporated county areas.

4. Achievement of Project Objectives

In terms of the project's stated objectives, this alternative does not satisfy several: It would not provide a suitable plan for "further progress" within Riverside County since it posits no growth and no development. Nor would it address new needs, since it pushes all new growth into the cities where Riverside County's General Plan does not apply. It would provide updated technical data, simply by definition, but would not provide any updated land

uses within Riverside County (since no further development would be permitted). And, most particularly, it does not further the Riverside County Vision in any way since it does not permit or promote any "continued progress" within the county.

5. Conclusions

Overall, the No Build/No Growth Alternative would "substantially lessen" most of the significant environmental impacts within the unincorporated portions of Riverside County, as indicated in Table 6.4-B. In a few areas under this alternative, however, a number of existing impacts would remain significant and would not be mitigated. These include: increased traffic network congestion and inadequate levels of service and groundwater depletion.

In addition, new impacts would arise where future conditions do not conform to regulatory conditions. In particular, these include: conflicts with greenhouse gas reduction plans (particularly AB 32 and the associated CARB Scoping Plan) and increasingly inefficient uses of energy (particularly electricity) as a result of failure to implement the CARB Scoping Plan, the proposed CAP, new California State Title 24 energy efficiency standards, and other related plans.

Taken together, the substantial reduction in significant impacts associated with this alternative would make it appear to be the "environmentally superior" alternative addressed under CEQA. However, Section 15126.6(e)(2) of the State CEQA Guidelines notes, "If the environmentally superior alternative is the 'no project' alternative, the EIR shall also identify an environmentally superior alternative among the other alternatives."

In addition, as outlined above, this alternative meets only one of five of the objectives of the project. This means that this alternative is not an acceptable means for achieving the stated project objectives. For all of these reasons, despite being found "environmentally superior" to the proposed project, the No Build/No Growth Alternative is not deemed the preferred alternative.

B. No Project / Status Quo Alternative

As noted under the previous alternative, CEQA specifies a no-project alternative that "would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with the available infrastructure and community services" (State CEQA Guidelines, Section 15126.6(e)). Accordingly, the No Project / Status Quo Alternative examines the environmental effects associated with abandoning the proposed project, GPA No. 960, and "doing nothing," that is, allowing the unincorporated county to continue to develop as planned under the existing Riverside County General Plan.

Again, as with the first alternative, analysis of this alternative provides a look at the environmental cost of maintaining the status quo. As such, this alternative serves as a lens for highlighting the environmental implications for approving (or denying) the proposed project.

1. Assumptions

For this alternative, it is assumed the updates to the General Plan proposed under GPA No. 960 would not be adopted. Instead, the existing (2008) General Plan would continue to be implemented and all of the general assumptions mentioned previously apply. Thus, this alternative examines the effects that would occur if

unincorporated Riverside County were to build out according to this existing plan. In addition, the No Project/Status Quo Alternative includes the following assumptions as part of its project description:

- GPA No. 960 (the proposed project) would not be approved and the technical and regulatory updates needed for the General Plan (e.g., statistical updates, resource mapping revisions, regulatory changes, etc.) would not be adopted. No alterations to the General Plan's existing land use policies or maps would occur. No LUD changes are made, no Rural Village Study Areas are updated or deleted, no new RVOs are created, and so on.

- The General Plan would not be updated to discuss climate change and greenhouse gas regulation. The draft CAP included with GPA No. 960 would not be adopted or implemented. Greenhouse gas issues would be addressed and mitigated, where necessary, on a case-by-case basis for individual implementing projects instead.

a. Baseline Assumptions

As with all of the other alternative (and the rest of the EIR for that matter), the starting baseline assumptions for the Status Quo Alternative are the existing physical conditions within Riverside County. Full details on these existing conditions are provided throughout the EIR and, in particular, conditions for each environmental issue are presented in the section addressing that topic. For example, Section 4.14 (Mineral Resources) provides information on existing mineral designations, mapped locations of mineral resources of regional or statewide significance, and so on within Riverside County. This baseline condition applies to both the incorporated and unincorporated portions of the county. See Table 6.4-C (No Project/Status Quo Alternative – Assumptions and Projections) for the full baseline data set used for this alternative. See the footnotes to this table for additional comments on the baseline assumptions.

b. Build Out Assumptions

For this particular alternative, it is assumed that no changes to the County General Plan are made and that the unincorporated portions of Riverside County build out as directed by the existing General Plan. As such, the set of build out projections developed generally for the existing General Plan apply. For the cities within Riverside County, growth is assumed to occur as directed by each city's individual General Plan. For the sake of consistency, the standardized city land use build out projections developed by RCCDR were applied to each of the individual cities within Riverside County. Thus, the build out conditions for this alternative are the build out assumptions made for the existing Riverside County General Plan. See Table 6.4-C for the full build out data set used for this alternative. See the footnotes to this table for additional comments on the build out assumptions.

For the regions outside the boundaries of Riverside County, land use and demographic assumptions used are those promulgated by SCAG for the six-county region, for example, RCP-10 and the SCAG 2012 Regional Transportation Plan.

As outlined elsewhere in this EIR, for example Table 4.3-F, build out of the existing General Plan would result in slightly more homes (roughly 2%), people (1.3%) and jobs (5.6%) compared to that which would result from build out of the General Plan as it would be if updated pursuant to GPA No. 960 (the "project scenario" for the purposes of this section's analysis). These higher values are mainly due to the increased densities and intensities called for in the Rural Village Study Areas outlined in the existing General Plan.

Specifically, development under this alternative would include the build out of certain areas with higher development potentials than planned for under the proposed project. These include the following:

- The Aguanga Rural Village Study Area encompasses roughly 6,000 acres under the existing General Plan. Under this alternative, the RVSA and its higher densities/intensities would remain in effect. (GPA No. 960 proposes it be deleted and the area continue to develop according to the existing underlying General Plan LUDs.) Thus, in this region the alternative would have the potential for greater impacts than those of the proposed project.

- The Anza RVSA encompasses roughly 71,000 acres under the existing General Plan. Again, under this alternative, the RVSA and its higher densities/intensities would remain in effect. A new, more general policy area would not replace the RVSA, as proposed by GPA No. 960. As with Aguanga, in this region the alternative would have the potential for greater impacts than those of the proposed project.

- The El Cariso RVSA, encompassing roughly 200 acres under the existing General Plan, would continue to be in effect under this alternative. (It would be deleted under GPA No. 960.) This means increased development potential would still exist for this area.

- The San Jacinto Agriculture/Potential Development Study Area, encompassing roughly 8,000 acres under the existing General Plan, would continue to be in effect under this alternative. (It would be deleted under GPA No. 960.) This means increased development potential would continue to exist for this area.

Table 6.4-C: No Project / Status Quo Alternative – Assumptions and Projections

No Project/ Status Quo Alt. ASSUMPTIONS [5]	Baseline: Existing (2007) Conditions[1, 2]			Build out: Future (2060) Conditions[1,2 4]

Footnotes:

1. Source for land use, existing and build out: EIR Table 4.2-F for all except "Cities, Build out," which were estimated from RCCDR 2012 data.
2. Source for socioeconomic data: EIR Table 4.3-G.
3. Since their incorporations occurred after the date of NOP issuance for this EIR, the cities of Eastvale and Jurupa Valley are generally included in the unincorporated Riverside County totals, rather than the incorporated totals for baseline conditions. Category totals estimated from proportional growth projections.
4. "Build out" conditions are those projected at full realization of the alternative's land use plans. For this alternative, the build out scenario includes the following assumptions:
   a. No new development occurs in the unincorporated portion of Riverside County (that is, build out values equal the baseline values). Also, no additional unincorporated lands are annexed into any cities.
   b. The incorporated portions of Riverside County fully develop (build out) according to the land uses mapped in the existing General Plans for the individual cities (as interpreted by RCCDR).
   c. The cities of Eastvale and Jurupa Valley are generally included in the incorporated build out totals.
5. All values rounded to the nearest hundred. Thus, totals may not sum precisely.

6. Commercial uses include commercial-retail, commercial-office, commercial-tourist, community center and MUPA (mixed-use).
7. Industrial uses include heavy and light industry, business parks, warehouses and public facilities, as well as mining and (active) recreational uses.
8. Open space uses include conservation lands, as well as water (lakes, reservoirs, etc.).
9. "Other" uses encompass any not listed elsewhere and include freeways, roads, canals, etc., as well as vacant (undeveloped) lands.

Source: See footnotes, above, for data sources.

2. Environmental Implications

As noted previously, CEQA allows "a matrix" to be used to summarize "the major characteristics and significant environmental effects of each alternative." With this in mind, in addition to the basic land use and socioeconomic data presented above, a second table (Table 6.4-D (No Project/Status Quo Alternative – Environmental Effects Summary), below) was created to briefly indicate the environmental effects projected for the given alternative. Where significant effects arise, they are discussed in detail following the table.

Because it does not include the reductions associated with GPA No. 960's proposed Rural Village Study Area changes, build out under this alternative would generally result in slightly greater adverse environmental impacts than that associated with the project. In particular, this alternative does not address new environmental concerns, such as greenhouse gas emissions, traffic (VMT) reductions, energy conservation or water conservation. In some areas, such as certain types of air pollution, noise exposure and traffic levels, existing (baseline) environmental effects are already at a significant level and the alternative would not relieve or lessen these impacts. All of these issues are discussed in greater detail below.

As shown in Table 6.4-D, this alternative would have a number of significant environmental effects (either individual, in localized areas or cumulative). Certain of these significant environmental effects would be substantially worse than those associated with the project-updated General Plan. These effects, which are discussed further below, include:

- Adverse effects to existing visual character, light and glare, and other aesthetic effects.
- Increased greenhouse gas emissions and conflicts with existing regulations seeking to reduce greenhouse gases.
- Impacts to biota and sensitive biological resources in areas not covered by a MSCHP.
- Inefficient use of energy.
- Increased people and property exposed to excess noise.
- Circulation system effectiveness and congestion management conflicts.
- Increased demand on existing water supplies and need for additional water.
- Groundwater depletion or overdraft.
- Population increase straining community services or facilities.
- Facilitation of other activities leading to significant environmental effects (in particular, increasing the rate of growth within the cities of Riverside County and surrounding cities and counties; see discussion, below).

Table 6.4-D: No Project/Status Quo Alternative – Environmental Effects Summary

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
4.2 – Land Use							
4.2.A	Physically divide an established community.		•				=
4.2.B	Conflict with land use policies intended to avoid or mitigate an environmental effect.		•				=
4.2.C	Conflict with any habitat conservation plan or natural community conservation plan.		•				=
4.3 – Population and Housing							
4.3.A	Induce direct or indirect population growth.		•			•	↑
4.3.B	Displace residential units.		•				=
4.3.C	Displace people.		•				=
4.4 – Aesthetic and Visual Resources							
4.4.A	Adversely affect scenic vistas.			•		•	↑
4.4.B	Adversely affect scenic resources within State Scenic Highways.			•			↑
4.4.C	Adversely affect existing visual character.						↑
4.4.D	Cause adverse light and glare effects.		•			•	↑
4.4.E	Interfere with nighttime use of the Palomar Astronomical Observatory.		•				↑
4.5 – Agricultural and Forestry Resources							
4.5.A	Cause the direct or indirect conversion of designated Farmlands.				•	•	↑
4.5.B	Encroach on or conflict with existing agricultural uses.				•	•	↑
4.5.C	Adversely affect forest lands and forestry uses.		•				=
4.6 – Air Quality							
4.6.A	Conflict with air quality plans.			•			=
4.6.B (1)	Cause significant construction (short-term) air emissions.				•	•	↑
4.6.B (2)	Cause significant operational (long-term) air emissions.				•	•	↑
4.6.C	Cause cumulatively significant project air quality impacts.				•	◊	↑
4.6.D	Expose sensitive receptors to air pollutants.				•	•	↑
4.6.E	Expose substantial numbers of people to objectionable odors.			•			=
4.7 – Greenhouse Gases							
4.7.A	Generate substantial greenhouse gas emissions.						↑
4.7.B	Conflict with greenhouse gas reduction plans, policies or regulations.						↑
4.8 – Biological Resources							
4.8.A	Adversely affect riparian or other sensitive habitats.						↑
4.8.B	Cause direct and indirect impacts to protected species or their habitats.						↑
4.8.C	Adversely affect wetlands.						↑
4.8.D	Impede species movement, migration, wildlife corridors or use of wildlife nursery sites.						↑
4.8.E	Conflict with adopted habitat conservation plans.		•				=
4.8.F	Conflict with local biological resource protection policies or ordinances.		•				=
4.9 – Cultural and Paleontological Resources							
4.9.A	Adversely change the significance of historical resources.			•			↑
4.9.B	Cause the destruction of known archeological resources.			•		•	↑

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
4.9.C	Cause the destruction of unique paleontological resources or sites.		•			•	↑
4.9.D	Result in the disturbance of human remains.			•			↑
4.10 – Energy Resources							
4.10.A	Increase demand for electricity.			•		•	↑
4.10.B	Increase demand for natural gas.			•		•	↑
4.10.C	Cause the inefficient use of energy.						↑
4.11 – Flood and Dam Inundation Hazards							
4.11.A	Result in housing within flood hazard areas.			•			↑
4.11.B	Cause impediment of flows.			•			↑
4.11.C	Expose people or structures to flooding hazards, including flooding due to dam or levee failure.			•			↑
4.11.D	Cause the adverse alteration of drainage patterns or substantially increase surface runoff.			•			↑
4.11.E	Cause inundation risks due to seiche, tsunami or mudflow.		•				=
4.12 – Geology and Soils							
4.12.A	Expose people or structures to substantial adverse effects due to rupture or a known earthquake fault.			•			↑
4.12.B	Expose people or structures to substantial strong seismic groundshaking.			•		•	↑
4.12.C	Expose people or structures to substantial adverse effects due to seismic-related ground failure, including liquefaction.			•			↑
4.12.D	Expose people or structures to substantial adverse effects due to landslide.		•			•	↑
4.12.E	Result in substantial soil erosion or topsoil loss.			•			↑
4.12.F	Result in development on unstable geological units or soils.		•				↑
4.12.G	Result in development on expansive soil.			•			↑
4.12.H	Result in development on soils incapable of supporting septic tanks or alternative wastewater disposal systems.			•			↑
4.13 – Hazardous Materials and Safety							
4.13.A	Create a significant hazard through the routine transport, use or disposal of hazardous materials.		•				↑
4.13.B	Cause a significant hazard through the accidental release of hazardous materials.		•				↑
4.13.C	Result in hazardous emissions or related hazards within ¼-mile of a school.		•				↑
4.13.D	Result in a significant hazard due to development on a Cortese List hazardous materials site.		•				↑
4.13.E	Result in a safety hazard for people within a two-mile radius of a public or public use airport.		•				↑
4.13.F	Result in a safety hazard in the vicinity of a private airstrip or heliport.		•				↑
4.13.G	Impair or interfere with adopted emergency response or evacuation plans.		•				↑
4.13.H	Expose people or structures to significant risk due to wildland fire.		•			•	↑
4.14 – Mineral Resources							
4.14.A	Result in the loss of availability of delineated locally important minerals.	•					=
4.14.B	Result in the loss of availability of known mineral resources.		•				↓
4.15 – Noise							
4.15.A	Generate noise or cause noise exposure in excess of standards.				•	◊	↑
4.15.B	Generate or cause exposure to excessive groundborne vibration.			•			↑

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
4.15.C	Result in a substantial permanent increase in ambient noise levels.				•	•	↑
4.15.D	Result in a substantial temporary or periodic increase in ambient noise.				•	◊	↑
4.15.E	Expose people to excessive airport-related noise levels.		•				↑
4.16 – Parks and Recreation							
4.16.A	Increase the use of existing parks or recreational facilities resulting in their substantial physical deterioration.		•			•	↑
4.16.B	Trigger growth effects resulting in the need for additional parks or recreational facilities.		•				↑
4.16.C	Result in significant adverse effects due to the need for additional parks or recreational facilities.		•				↑
4.17 – Public Facilities							
4.17.A	Cause adverse environmental effects due to the need for fire protection services.		•			•	↑
4.17.B	Cause adverse environmental effects due to the need for law enforcement services.			•		•	↑
4.17.C(1)	Adversely affect or exceed the permitted capacity of a landfill.			•		•	↑
4.17.C(2)	Cause inconsistencies with applicable statutes and regulations related to solid waste, including the County Integrated Waste Management Plan.		•				↑
4.17.D	Cause adverse environmental effects due to the need for schools.		•			•	↑
4.17.E	Cause adverse environmental effects due to the need for library services.			•		•	↑
4.17.F	Cause adverse environmental effects due to the need for medical facilities.			•		•	↑
4.18 – Transportation and Traffic							
4.18.A	Conflict with circulation system effectiveness regulations for any transportation, including vehicular, mass transit and non-motorized travel.				◊		↑
4.18.B	Conflict with a congestion management program, including level of service (LOS) standards and travel demand measures.				◊	◊	↑
4.18.C	Cause substantial safety risks as a result of a change in air traffic patterns.		•				=
4.18.D	Cause substantial alterations in waterborne, rail or air traffic.		•				=
4.18.E	Substantially increase road hazards due to design or incompatible uses.		•				=
4.18.F	Cause an adverse effect on or need for new or altered road maintenance.		•				=
4.18.G	Cause an adverse effect on circulation during construction.		•				=
4.18.H	Result in inadequate emergency access.		•				↑
4.18.I	Conflict with policies for public transit or non-motorized travel, or decrease the performance or safety of such facilities.		•				=
4.19 – Water Resources							
4.19.A	Result in insufficient water supply.				•	◊	↑
4.19.B	Substantially deplete groundwater supplies or substantially interfere with groundwater recharge.				•	◊	↑
4.19.C	Substantially degrade water quality.			•			↑
4.19.D	Violate water quality standards or waste discharge requirements.			•			↑
4.19.E	Exceed wastewater treatment requirements.		•				=
4.19.F	Exceed wastewater treatment capacity.		•				=
4.19.G	Result in significant adverse effects due to the construction of new or expanded water or wastewater facilities.		•				↑
4.19.H	Substantially alter existing drainage patterns resulting in substantial erosion or siltation.			•			↑

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
4.19.I	Cause runoff exceeding stormwater drainage system capacities or cause substantial water pollution.			•		•	↑
4.19.J	Cause significant adverse effects due to the need for new or expanded stormwater drainage facilities.			•		•	↑
5.2 – Significant Irreversible Changes							
5.2.A	Result in a large commitment of non-renewable resources that make later removal or non-use unlikely.		•			•	=
5.2.B	Result in the unjustified commitment of irretrievable resources.		•				=
5.2.C	Result in primary or secondary impacts that generally commit future generations to similar uses.				•	•	=
5.2.D	Result in an environmental accident that could cause irreversible damage.		•				=
5.4 – Significant Growth-Inducing Effects							
5.4.A	Foster direct or indirect economic growth.				•	•	↑
5.4.B	Foster direct or indirect population growth.				•	•	↑
5.4.C	Result in construction of additional housing.				•	•	↑
5.4.D	Remove obstacles to population growth.		•				↑
5.4.E	Facilitate other activities leading to significant environmental effects; e.g., encroach into isolated or remote areas.				•	•	↑
5.4.F	Result in population increase that may strain community services or facilities.		•			◊	↑

Footnotes:
1. Impacts are based on a comparison of the effects of build out of the alternative as compared to the environmental baseline. Unless noted otherwise in the text, the environmental baseline is assumed to be the same as or substantially similar to that described for the proposed project in Sections 4.0 through 5.0 of the EIR.
2. Only impacts requiring new CEQA-specific mitigation measures to reduce their impacts to less than significant are considered to be "less than significant with mitigation." (Compliance with existing laws, ordinances, regulations, etc., is assumed under CEQA.)
3. Diamond (◊) denotes an impact that is substantially greater than for the General Plan as updated per GPA No. 960.
4. Severity of projected impacts relative to proposed project (rather than environmental baseline), for comparison purposes: ↓, less severe; ↑, more severe; ↓↑ = areas of each result; and, **=** , approximately the same.
5. Shaded yellow boxes denote impact finding for build out of the General Plan with GPA No. 960 (per Table 5.5-AJ) for comparison.

Source: Riverside County Planning Dept., new analysis and results from EIR Sections 4.2 - 4.19 and 5.1 - 5.5, 2012.

a. General Impacts

The severity of the environmental impacts for this alternative, which is essentially build out of Riverside County as planned in the existing General Plan, are based on the impacts disclosed in EIR No. 441, which was certified for the existing RCIP General Plan in October of 2003. Where predicted impacts of this alternative diverge from those in EIR No. 441 (mainly to reflect subsequent growth patterns and updated projections), they are discussed further below.

As indicated in Table 6.4-D, the No Project/Status Quo Alternative would generally have environmental effects within unincorporated Riverside County similar to, but slightly greater than, that of the proposed project because of the greater development potential proposed under that plan (compared to GPA No. 960). These areas of increased development potential would collectively result in a build out scenario that generates roughly 8,000 more dwelling units, 24,000 more people and 30,000 more jobs (and the land uses that provide the source of this employment).

These slightly higher levels of development would result in a slightly greater development footprint with a corresponding increase in the potential for adverse spatial effects to the environment. Thus, this means this alternative would have slightly greater impacts to spatially based environmental resources, such as scenic, agricultural, mineral, biological and cultural resources. Geological and hydrological effects also fall into this category. See Table 6.4-D for a complete list of impacts, including spatial effects. Though slightly higher than the proposed project, in most cases impacts are roughly similar in significance to those predicted for build out of the General Plan pursuant to GPA No. 960. The exceptions are described further below.

In addition to spatial impacts, the slightly higher population and employment proposed under this alternative would also have environmental effects in unincorporated Riverside County. It would slightly increase demand on existing facilities, such as schools, wastewater treatment facilities, parks, water supplies and delivery infrastructure, solid waste disposal and so on. It would also slightly increase the demand for services, such as fire protection, law enforcement and medical, libraries and government services. These increased demands would also trigger the need for new public facilities, services and infrastructure accordingly.

Traffic and related effects, which are also projected off population and employment data, would also be slightly higher than the proposed project's. The existing General Plan identifies impacts to traffic, such as congestion and unacceptable levels of service on roadways, as a significant and unavoidable impact of development in Riverside County. Air quality impacts, particularly those resulting from mobile sources (that is, vehicles) would also be significant and unavoidable under this alternative. These issues are discussed in greater detail below.

b. Aesthetic and Visual Impacts

As noted in Table 6.4-D, this alternative would have significant unavoidable adverse effects on the visual character of Riverside County. Specifically, EIR No. 441 indicates that build out of the existing General Plan would "result in conversion of open space areas to urban land use" causing the "obstruction of existing open views as well as potentially obstructing distant panoramic views" and "contribut[ing] significantly to the loss of visual character of the county" (from page 6 of the 2003 "Findings of Fact for Riverside General Plan - Impacts and Mitigation Measures" document). With its higher development potential and larger footprint, several aesthetic impacts would be worse for this alternative than compared to that of the proposed project. In particular, Impact 4.4.C (affecting visual character) for this alternative would be much worse than for the project and would represent a new impact for this alternative. The proposed project would also result in cumulatively significant aesthetic impacts to scenic vistas (see Section 4.4, Aesthetics and Visual Resources, for more details).

c. Agricultural Impacts

With its slightly larger development potential and footprint, this alternative's impacts on agriculture would be slightly worse than that of the proposed project. As per EIR No. 441, this alternative would "result in the conversion of prime farmlands, unique farmlands, farmland of statewide importance [and] land actively utilized for agricultural production to a variety of non-agricultural uses" (Findings of Fact document, page 2). This impact would be significant and unavoidable with no feasible mitigation measures or alternatives to reduce this impact, according to EIR No. 441. This alternative would also result in significant impacts to designated farmlands due to their conversion to non-agricultural uses and due to conflicts between existing agricultural and non-agricultural uses. See Section 4.5, Agricultural and Forestry Resources, for more details.

d. Biological Impacts

EIR No. 441 was certified prior to the full implementation of the Western Riverside County MSHCP and its sister plan, the Coachella Valley MSHCP. As a result, EIR No. 441 necessarily found that build out of Riverside County would result in cumulatively significant adverse impacts on a variety of biological resources. Key among these were protected species (threatened, endangered, etc.) and their habitat, as well as other sensitive habitats, wetlands and wildlife movement corridors. Mitigation measures were included in EIR No. 441 to address impacts on a project-by-project basis at the implement stage, but the regional impacts, which could not be addressed in this manner, would remain significant and unavoidable sans the MSHCPs. The subsequent adoption and implementation of the two regional MSHCPs for Riverside County ensure that these cumulative impacts, as well as site-specific ones within the areas covered by the MSHCPs, would be less than significant. Table 6.4-D reflects these changes in cumulative impact findings (i.e., they can now be mitigated to less than significant through MSHCP compliance).

EIR No. 441 also finds that where coverage is not provided by an HCP, significant impacts to natural habitats could occur because the policies of the General Plan "do not specify a means for identifying habitats that warrant such measures" for the avoidance and minimization of impacts (per page 13, Findings of Facts document). The EIR for the RCIP General Plan was not able to fully provide the necessary mitigation measures since the MSHCP processes were not complete at that time. For GPA No. 960, however, the two existing MSHCPs provide the framework and scientific data necessary to permit the formulation of adequate mitigation measures for future development projects located outside the coverage areas of the two plans. The two MSHCPs mitigate for regional and cumulative impacts in Riverside County.

However, GPA No. 960 also includes additional CEQA-specific mitigation measures to ensure the proposed project's biological impacts would all be less than significant. (See Section 4.8, Biological Resources.) Lacking the additional biological mitigation measures that GPA No. 960 would include, the No Project/Status Quo Alternative would have greater impacts on Riverside County's biological resources than would the proposed project. The new significant impacts are reflected in Table 6.4-D accordingly.

e. Air Quality Impacts

In terms of air quality, this alternative would have slightly greater impacts due to the associated small increase in development potential, population, jobs and resultant traffic (VMTs). Under EIR No. 441, build out of Riverside County was found to be associated with several significant and unavoidable air quality impacts, even after the implementation of all feasible mitigation. Significant short-term air quality emissions, particularly of fugitive dust (PM_{10}), would occur during construction activities, such as site preparation. Likewise, significant long-term air pollutant emissions would occur from stationary sources as a result of development within Riverside County in a manner that could not be quantified at that time and thus, was assumed could exceed applicable air quality standards or otherwise be inconsistent with standards and air quality management plans.

Build out of the existing General Plan was also found to result in "changes in regional vehicular traffic trips and associated VMT" that would contribute to significant pollution levels. According to Tables 4.5.M, N and O in EIR No. 441, this includes pollutant levels exceeding SCAQMD thresholds for carbon monoxide (CO), reactive organic compounds (ROC), nitrous oxides (NO_x) and fugitive dust (PM_{10}). These effects would be significant for both western Riverside County and the Coachella Valley region. They would even significantly affect the central San Jacinto Mountains region and reach as far east as the Blythe on Riverside County's border with Arizona.

Lastly, although found to be less than significant under EIR No. 441, it is possible based on more recent modeling data (such as in Sections 4.6 and 4.18 of this EIR) that build out of this alternative would result in

significant air quality impacts to sensitive receptors. In areas where traffic levels would increase significantly, future new development would be required to incorporate adequate setbacks, anti-idling prohibitions or other measures to avoid significant effects to sensitive receptors, such as children, the elderly and the infirm, associated with houses and backyards, parks and playgrounds, schools, daycare centers, medical facilities and long-term care facilities (nursing homes, retirement homes, rehabilitation centers, etc.). In existing locations, however, increases in traffic would expose additional sensitive receptors to significant pollutant emissions. Further, due to the widespread and incremental nature of such pollutant increases, mitigation of such impacts are not possible at the implementing project stage beyond measures directly associated with facility or roadway citing. That is, setbacks and the like would only be effective in preventing exposure to or from new uses. They would not help existing uses, such as residential units, schools and care centers, that are located along existing highways and intersections where pollutant levels would be increasing incrementally over time as traffic increases in the county.

f. Greenhouse Gas and Energy Conservation Impacts

As with air pollutants, this alternative would generate slightly more GHG emissions than the proposed project due to the associated small increase in development potential, population, jobs and resultant traffic. Since the existing General Plan was originally adopted prior to the establishment of the various GHG reduction policies, programs and goals in California, it does not currently address the issue. Likewise, nor did the associated EIR, EIR No. 441 certified for the 2003 RCIP General Plan adoption, address GHGs.

As with the proposed project, on a countywide basis, GHG emissions would be cumulatively significant without mitigation. According to the GHG Study prepared for the project, the "business as usual" scenario in which unincorporated Riverside County builds out according to the existing General Plan (and, hence, this alternative) would result in the emission of roughly 19.75 million metric tons (MT) of carbon dioxide equivalents (CO_2e, a generic measure of GHGs) annually. According to previously published opinions issued by the Southern California Air Quality Management District (SCAQMD), any project emitting more than 3,000 to 10,000 MT CO_2e per year (MTY) or emitting 100% of the Business As Usual (BAU) scenario level, is considered to emit significant amounts of GHGs. Thus, in cases in which individual future development project approved pursuant to the existing General Plan would exceed these limits, and not be reduced to below BAU levels, individual GHG emissions would also be significant.

Lastly, the State of California has established (pursuant to AB 32, the 2006 Global Warming Solutions Act) a policy targeting the reduction of GHG emissions statewide to 1990 levels by 2020 and to 80% below 1990 levels by 2050. In order to be consistent with this state policy, the County of Riverside would need to reduce GHG emissions by roughly 3.2 MT per year by 2020. The proposed project is accompanied by a CAP that outlines and establishes a plan for achieving this reduction for Riverside County. The existing General Plan does not achieve this, thus this alternative would not meet the reduction needs identified to prevent significant GHG impacts from occurring within Riverside County.

In addition, the proposed CAP addresses energy conservation (i.e., decreasing electricity and natural gas usage) as a means for decreasing GHG emissions. As such, it includes a variety of measures that increase energy efficiency and conservation for both existing and new (future) uses within Riverside County. Implementation of both types of measures will be necessary to achieve Riverside County's CAP goals. Accordingly, without this program, the existing General Plan does not encompass the energy efficiency reduction needs of the CAP. Even though new development would be required individually to meet the enhanced energy efficiency standards of the State of California's current Green Building Codes (i.e., commonly referred to as "Title 24"), this would not help improve energy efficiency for the thousands of existing homes and businesses already in Riverside County, particularly those constructed prior to the 1974 establishment of Title 24 energy requirements for buildings. As such, this alternative does not address existing energy use in a manner that would ensure its efficient use and conservation

of energy. For this reason, the alternative was found to have a significant impact on energy due to its inefficient use. This impact is greater for this alternative than it would be for the proposed project, which is accompanied by the CAP.

g. Traffic and Circulation Impacts

As alluded to above, in terms of traffic when an area's population or its sources of employment (or other trip attractors, e.g., shopping malls, casinos, universities, etc.) increase, there is typically an associated increase in vehicle miles traveled. As the number of vehicles using a network increase, so too must the network's available roadway capacity in order to ensure adequate levels of service (LOS) are maintained along both the network's roadway segments and at the intersections that link these segments.

In areas where existing roadway capacities are already functioning at unacceptable levels (e.g., LOS F), any additional increases in traffic would contribute incrementally to cumulatively significant impacts. For existing roadways with currently acceptable functioning levels, increasing traffic volumes without any corresponding expansion of network capacity could eventually lead to unacceptable LOS and significant congestion. Even future roadways constructed with capacity sufficient to serve their initial needs would suffer similar impacts as traffic continued to increase regionally over time, if it increased beyond that planned for the area's build out (and, hence, its roadway network).

As outlined more fully in Section 4.18 (Transportation and Circulation), all of these elements contribute to the significant impacts that would occur for certain existing and projected future roadway facilities within Riverside County. For these reasons, EIR No. 441 found that future growth in Riverside County as the existing General Plan was implemented would have significant, unavoidable impacts on certain portions of the county roadway network. It would also have similar impacts on certain stretches of freeway, that is, state and federal roadways outside Riverside County's jurisdiction to control and ability to mitigate. As such, this alternative was found to have significant impacts, both individually and cumulatively, in regards to circulation system effectiveness and congestion management (including the attainment of acceptable LOS) throughout Riverside County.

Under this alternative, the network of roads proposed in the Riverside County General Plan (i.e., General Plan Figure C-1) also would not be updated to reflect current conditions and needs. The circulation network would still be implemented, but only with the roadways proposed in the existing General Plan. Since the network would not be subject to the revisions proposed under GPA No. 960, development of the existing network would, by definition, have slightly greater traffic impacts. It would not achieve the circulation improvements that implementation of the newer network under GPA No. 960 would provide.

Lastly, while equal to or worse than the proposed project in most areas, this alternative is projected to have *less* significant traffic impacts than the proposed project in the area of temporal (short-term) traffic impacts (as reflected by Impact 4.18.A). As used here, temporal traffic impacts are those that occur in the interval between a roadway being identified as operating at an unacceptable LOS and that same roadway being improved in the manner necessary to bring the level of service back up to acceptability (for example, through road widening, the addition of an left-turn lane, a stop sign or a new signal at an intersection, or even the construction of an additional parallel road). In addition to the actual effects of congestion, these temporal traffic impacts could also result in temporarily significant increases in noise or air pollutant levels (for example, carbon monoxide "hot spots" that arise at heavily congested intersections).

Depending on the process triggered (i.e., private development requirements for construction, payment of TUMF fees to be used by the County of Riverside in enacting scheduled network improvements programmatically or improvements by RCTC, Caltrans or FHWA), the interval during which temporal traffic impacts would occur

before the necessary improvements were accomplished could be anywhere from weeks to months or even years. A Transportation Improvement Plan (TIP) addressing five years of future transportation improvement spending is updated annually by the County of Riverside and outlines the prioritization of the various competing roadway network improvements needed.

Under the existing General Plan's level of service specifications (i.e., General Plan Figure C-3), improvements are triggered when a roadway segment is found to be operating at LOS D or LOS E as defined by the figure's traffic volumes (average daily trips (ADT) for maximum two-way volumes). See Section 4.18 (Transportation and Circulation) for specifics. As proposed in GPA No. 960, these levels would be adjusted to lower the ranges for four-lane Mountain Arterials and extend (widen) the ADT ranges for many other roadway types (e.g., Arterial, Urban Arterials, Expressways, Freeways and Ramps). See Table 4.18-D for specifics. The traffic levels on the various network roadways would not change as a result of this revision, as these levels are generated by existing and future land uses both within and outside of Riverside County. Only the definitions associated with LOS C, D and E for certain road types would change. The broader ranges proposed, however, would result in an increase in the duration of temporal traffic impacts occurring along unimproved roadways.

Thus, because it uses the prior General Plan policies, the No Project/Status Quo Alternative would reduce the temporal traffic impacts associated with the proposed project. It would have less of a temporal traffic impact, as well as less associated noise and air quality impacts, than build out of the General Plan as updated by the proposed project, GPA No. 960.

h. Noise Impacts

For the existing General Plan, EIR No. 441 concluded that its mitigation measures would be sufficient to ensure that any noise impacts were reduced to less-than-significant levels. However, in some locations within Riverside County, current noise levels already exceed acceptable levels. As such, additional noise from future development would result in significant environmental noise impacts. EIR No. 441 notwithstanding, this alternative would have significant impacts due to exceeded noise standards, as well as due to substantial permanent and temporary noise increases.

As with air quality, this alternative would have slightly greater noise impacts than the proposed project due to the associated small increase in development potential, population, jobs and resultant traffic. Motor vehicle travel is the largest single source of noise generation in Riverside County and directly affects noise levels for receptors along roadways. As such, as traffic levels increase, noise levels affecting existing homes and other sensitive uses also increase incrementally. However, due to the widespread, incremental nature of these increases, it is not possible to avoid or mitigate such impacts to the thousands of homes and other uses that would ultimately be exposed to excessive noise levels over time. As such, it is assumed that, EIR No. 441 notwithstanding, future increases in long-term (operational) ambient noise, as well as short-term (construction) noise, that exceed standards would be cumulatively significant under this alternative. Overall, however, as noted in Table 6.4-D, the severity of all noise impacts associated with this alternative mirrors that expected for build out of the General Plan as amended by GPA No. 960.

i. Parks and Recreation Impacts

For the existing General Plan, EIR No. 441 concluded that its mitigation measures would be sufficient to ensure any impacts to existing or future parks and recreational facilities were reduced to less-than-significant levels. As with the other effects, this alternative would have slightly greater impacts than the proposed project due to the associated small increase in population resulting from the slight increase in residential development potential.

Although EIR No. 441 did not find General Plan build out would result in significant cumulative effects, this alternative is associated with a potentially significant cumulative effect on existing recreational facilities due to increased use.

j. Water Impacts

The slightly higher development potential associated with this alternative would mean that additional (future) demands are likewise slightly higher. In general, this means that additional potable water supplies and the infrastructure to treat and deliver such water would be needed within unincorporated Riverside County beyond already identified existing needs.

As outlined in Section 4.19.4.D, some portions of Riverside County already upon tightly constrained water resources. These include adjudicated groundwater basins (e.g., Temecula-Murrieta Basin, Riverside-Arlington Basin, Rialto-Colton Basin, etc.) and imported State Water Project (SWP) water (e.g., member agencies of the Metropolitan Water District of Southern California, such as Eastern and Western Municipal Water Districts and the retail suppliers to which they wholesale water). SWP water is apportioned out by the State of California (Department of Water Resources) according to a set of contractual priorities based on availability. As the water supply is greatly dependent upon the snow levels in the Sierra Nevada Mountains, imported water availability can vary greatly based upon annual snowfall and precipitation levels.

Thus, future development could result in significant impacts on existing water supplies (either imported or groundwater) if in a location already using water in excess of supply, i.e., drawing down a groundwater basin or, as is more common, exceeding future water availability. Where increases would be served by existing groundwater supplies, this would also result in significant drawdown or overdraft of existing groundwater basins. And, even in cases where the additional basin drawdown itself was not significant, it is likely that such increased use would contribute incrementally to a cumulatively significant impact on water basins already in overdraft or where the current basin withdrawals exceed its replenishment (which would eventually lead to depletion of the basin). Since California's water supply is finite and the State of California has identified critical constraints related to imported water availability, build out of Riverside County pursuant to this alternative would result in cumulatively significant impacts on imported water supplies.

k. Significant Cumulative Impacts

In general, most of the impacts found cumulatively significant for the proposed project are substantially similar to those that would occur for this alternative. However, as shown in Table 6.4-D, there are a few exceptions. For this alternative, new cumulatively significant impacts (i.e., those above that associated with the proposed project) would be associated with: changes to existing visual character, greenhouse gas emissions and regulatory conflicts, and inefficient use of energy. This alternative would also increase the number people and structures introduced into a region of California with known seismic and related geological hazards. On a cumulative basis, significant effects would be akin to those described for the project, but of increased scope based on the larger development capacity of the existing General Plan (as compared to the project's). Similarly, this alternative's impacts to public facilities would be similar to that of the project, but with correspondingly larger effects.

l. Growth Inducement

As clearly outlined above, with its slightly larger development potential and footprint, the No Project / Status Quo Alternative would accommodate a slightly larger population and workforce than the proposed project. As such, this alternative's growth-inducing effects would also be slightly higher than the project. Similar to that of

the project, most of this alternative's growth-inducing impacts would be significant and unavoidable. It would foster direct and indirect population growth and economic growth. This would also facilitate the construction of additional housing and lead to other significant environmental growth-related effects, such as encroachment into isolated areas and increased human trespass into remote areas.

m. Impacts to Cities

Under this alternative, it was assumed that growth within the cities would occur in accordance with each city's general plan as required by state law and the existing General Plan would dictate build out of unincorporated areas. See Table 6.4-C for RCCDR estimated build out results for incorporated Riverside County.

Though not addressed separately, the significant effects of this alternative on the cities within and adjacent to unincorporated Riverside County would be limited principally to cumulative effects caused by the incremental contributions arising from development in Riverside County. These significant cumulative effects would occur in areas where the additional contribution of future county development causes an impact to exceed a threshold or standard of acceptability. This would occur where development in unincorporated county areas bordered city areas or caused traffic, noise or other effects that carried over the municipal boundary. Significant cumulative effects to cities result from this alternative would include:

- Affects to scenic vistas and existing visual character within cities.
- Encroach on or conflict with existing agricultural uses within cities.
- Air quality effects where emissions occurring within Riverside County would affect air pollutant levels within cities, including for construction (short-term) and operational (long-term) emissions, particularly traffic-related emissions. Exposure of sensitive receptors within cities to air pollutants generated within Riverside County and cumulatively significant air quality impacts could also occur.
- Greenhouse gas emissions (to the extent that traffic generated by activities within the unincorporated county affected trips and congestion within cities).
- Noise level increases within Riverside County could affect levels within cities, including for construction (short-term) and operational (long-term) emissions. In particular, traffic-related noise increases could result in cities as a result of changes in county traffic patterns and/or increased trips.
- Where development within Riverside County would result in traffic increases, significant effects could occur in cities where links between city and county circulation networks interface. That is, increased traffic could affect cities in two ways: First, by causing traffic slowing on county roads that leads to slowing or backups on city roads. Second, when a county roadway becomes less able to accommodate traffic, drivers seeking alternate routes may end up traveling through cities. Lastly, development of land uses that attract visitors (such as regional shopping malls, medical centers, universities, casinos and other large-scale uses) within unincorporated Riverside County could increase trips on city roads that lead to/link to the use within the county.
- In locations where cities rely upon the same groundwater basins that also serve an unincorporated area, additional development within Riverside County could lead to significant demands on the existing water supply. Where a groundwater basin is already in overdraft or where future demands would exceed the recharge capability of the basin, both the city and county areas relying on the basin would be significantly affected.

- Where cities and unincorporated areas are both served by the same water district, additional development within Riverside County could increase demand on the existing imported water supply. Since such supplies are finite and subject to factors beyond the control of the water district (e.g., rainfall amounts, state mandates, court-ordered diversions for fish species in the Sacramento/San Joaquin Delta, etc.), increases exceeding the districts' ability to meet the need would result in significant impacts.

3. Achievement of Project Objectives

In terms of the project's stated objectives, this alternative does not satisfy several: It would not provide a suitable plan for further progress within Riverside County since it does not update the study areas identified in 2003 for future planning specifications. It does not include any LUD updates and thus does not address the updated land use objective. Since it does not address updated regulations that future development within Riverside County would need to comply with (e.g., AB 32 and greenhouse gas reduction planning), it does not satisfy the address new needs objective. It would provide updated technical data, simply by definition. Lastly, it does not further the Riverside County Vision in any way since it does not "enhance" or "extend" the "continued progress" within Riverside County.

4. Conclusions

The significant impacts within Riverside County associated with this alternative are generally substantially similar to those anticipated for the proposed project. This alternative, however, proposes slightly (roughly 2-6%) higher levels of population, housing, workforce and employment-generating land uses. As such, even in instances where both the project and this alternative have similarly significant impacts, this alternative would be slightly more severe than the project.

Thus, overall the No Project/Status Quo Alternative would cause slightly more significant environmental impacts within the unincorporated portions of Riverside County, as indicated in Table 6.4-D. It would also result in several new significant impacts where the proposed project's would be less than significant (e.g., cumulative impacts due to GHG emissions and GHG reduction plan inconsistencies, in particular).

Taken together, the significant new greenhouse gas impacts and slightly higher significant impacts across many areas of environmental concern mean this alternative is not the environmentally superior alternative. Further, as outlined above, this alternative meets only one of five of the objectives of the project. This means that this alternative is not an acceptable means for achieving the stated project objectives. For these reasons, the No Project/Status Quo Alternative is deemed not the preferred alternative.

C. Agricultural Emphasis Alternative

Between 2000 and 2006, Riverside County loss roughly 30% of its existing agricultural lands to conversions made in the face of increasing development pressure. Although agriculture is this county's largest industry in terms of dollars, agricultural decline continues as urban uses encroach upon agriculture operations and economic pressures (including the price of water supplies) make conditions ever more tenuous for Riverside County's farmers and ranchers.

Not surprisingly, one of the significant impacts of build out of either the existing General Plan or the General Plan as updated pursuant to GPA No. 960 (i.e., the proposed project for the purposes of the alternative analysis) is loss of agricultural lands to non-agricultural uses and encroachment of non-agricultural uses into agricultural

areas. Both EIR No. 441, certified for the 2003 RCIP General Plan, and this EIR for GPA No. 960, find these impacts to be significant and unavoidable. Hence, this alternative is proposed as a means for addressing (lessening) this significant impact. In addition, this alternative also addresses the cumulatively significant wildfire hazards associated with build out of the project or existing General Plan by shifting roughly 25,000 future homes from remote, wildfire-prone rural areas to more accessible urban/suburban regions.

1. Assumptions

Under the existing General Plan, LUD changes from the Agricultural Foundation (i.e., the Agriculture, AG, LUD) are mostly exempt from the restrictions of the Certainty System review cycle. With key exceptions, the Certainty System limits LUD changes from lower density/intensity Foundations to once every eight years. As an example: per the Certainty System, a proposal without extenuating circumstances to change a parcel's LUD from Rural Residential, which is in the Rural Foundation, to Medium Density Residential in the Community Development Foundation, would only be allowed during the eight-year window opening. For AG LUDs, however, the removal of land from the Agriculture Foundation is allowed to occur on a quarterly basis within any given year.

This Agricultural Emphasis Alternative posits a change in the General Plan that recognizes the development pressures threatening the agriculture industry in various communities of this region. And, as a result, places Agriculture Foundation amendments back with other Foundation Components in requiring adherence to the main eight-year General Plan Certainty System review cycle for all parts of Riverside County except the Eastern Coachella Valley Area Plan (ECVAP). For lands within the ECVAP, Agriculture Foundation amendment proposals would continue to be permitted on a quarterly basis. They would also, however, be required to set aside at least 50% of the site's existing agricultural lands to be preserved in permanent agricultural easements.

This provision was intended to allow agriculture operators the option to change the foundation and land use designation when agriculture operation becomes unviable. There are many factors in the decision to continue agricultural operation or to convert into urban uses, such as the cost of operation versus economic gain, water availability, favorable growing conditions, advancements in agronomy, urban encroachment, non-compatible uses, etc.

The development (build out) scenario developed for the Agricultural Emphasis Alternative is based on the existing (2008 for the purposes of this EIR) General Plan. To it, the following specific changes were applied:

Fish Farms: The changes proposed in GPA No. 960 to recognize and protect aquiculture (fish farms) in the Salton Sea region as agricultural uses are also made under this alternative. Specifically, a total of roughly 800 acres of lands currently designated by other, non-agricultural LUDs would be re-designated AG. (The LUDs changed include roughly 200 acres of single-family residential uses, 100 acres of multi-family residential uses, 200 acres of industrial uses and 300 acres of open space-water (OS-W), so designated because of their proximity to the shores of the Salton Sea.)

Open Space-Rural: The existing General Plan includes roughly 1,930,000 acres of lands designated as open space-rural (OS-RUR) which is associated with a minimum lot size of 20 acres per unit (per General Plan Table LU-4). According to General Plan Appendix E-1 (Table E-1), the average (midpoint) lot size for OS-RUR is 40 acres per unit. Because much of this land has limited access, utilities or other constraints, a basic assumption was applied that only 65% of the total area would be potentially suitable for rural residential (OS-RUR) development; the other 35% was assumed would remain vacant. This split left 1,254,400 acres in the residential OS-RUR category with the remaining 675,500 acres assumed to remain vacant. (Note, this development pattern assumption was applied equally to all of the alternatives considered in this Alternatives Analysis.)

The 65-35 split is based on the original analysis used to derive the mid-point assumptions established in General Plan Table E-1. The stated minimum lot size for OS-RUR is 20 acres, but the midpoint analysis shows the average lot size is twice that. This doubling in lot size indicates roughly 50% of land would not end up with its own unit under the midpoint scenario. Thus, a roughly 50-50 split was necessary in order to avoid drastically overestimating the number of homes that were likely to be realized in the most remote, rural portions of Riverside County. This is important because an artificially inflated residential total for the OS-RUR area would result in reallocation of an inappropriately high number of dwelling units to the urban and suburban portions of Riverside County (see "Rural Density Transfer," below). Conversely, the 50-50 value was adjusted to 65-35 to avoid underestimating the number of homes ultimately likely in the remote rural county, which would lead to underestimating the environmental impacts to these open space areas, particularly regarding biological resources. The 65-35 split ensures biological, cultural, geological and other spatial impacts associated with this alternative are estimated conservatively.

Additional Agricultural Uses: Since the OS-Rural land use category encompasses the most total acreage of any single Foundation (even after being reduced by 45%) and spans the breadth and width of unincorporated Riverside County, it was identified as a reasonable source for additional agricultural activities. Specific to this alternative, the 1,254,400 acres remaining in the residential OS-RUR category was split with 20% (250,900 acres) added to the AG land use designation and the 80% remainder (1,003,500 acres) added to the Open Space-Conservation (OS-C) land use category. This additional agricultural land would foster the continuance of a robust agri-based economy in Riverside County, while the additional open space would enhance Riverside County's biological conservation efforts and ensure sufficient buffering between the agricultural areas and other uses (both developed and open space). It is also assumed for this alternative that all existing agricultural lands remain in agricultural uses (i.e., undeveloped and vacant, fallow, cultivated or built up with agriculture-related uses).

Rural Density Transfer: Lastly, the transfer of 1,003,500 acres of OS-RUR to OS-C would result in a reduction in development potential of roughly 25,100 dwelling units (du) per General Plan Table E-1. (The other 20% would not lose housing potential since housing is allowed under the AG land use). To accommodate the lost units and ensure that private property retains value, this alternative would permit the transfer of development rights from the altered acreage to certain urban or suburban uses. The 25,100 du were transferred to the other residential uses within Riverside County, as follows:

- + 1,000 du to Rural Residential (shared among RR, RM and RD uses)
- + 10,000 du to Single-Family Residential (EDR/VLDR/LDR category)
- + 5,600 du to Single-Family Residential (MDR use)
- + 6,000 du to Multi-Family Residential (MHDR use)
- + 2,500 du to Multi-Family Residential (shared among HDR/VHDR/HHDR and the mixed use residential [MUPA / CC] category)

High Fire Hazard Reduction: In addition to addressing agricultural issues, this alternative is also designed to address wildfire hazards, which are a cumulatively significant hazard associated with the proposed project (as well as existing General Plan) build out. This alternative reduces the area developed as residential by shifting OS-RUR lands areas, which encompass a large amount of area in "high" or "very high" fire hazard severity zones (as indicated, for example, by Figure S-11 of the General Plan), to AG (20%) or OS-C (80%). Both these alternate designations are generally associated with much lower levels of development and, hence, wildfire hazards. Areas of OS-C, in particular, generally are not developable and thus provide substantial reductions in future wildfire

risks. In total, as a result of this change roughly 25,000 fewer homes would be introduced into the rural and remote portions of Riverside County. This would greatly reduce the increase in wildfire risks to people, property and structures, which benefits the entire region.

Additional Assumptions: All of the general assumptions outlined at the beginning of this section also apply. There are no exceptions or changes to them for this alternative, or additional assumptions beyond those already covered above.

a. Baseline Assumptions

As with all of the other alternatives, as well as the rest of the EIR for that matter, the starting baseline assumptions for the Agricultural Emphasis Alternative are the existing physical conditions within Riverside County. Full details on these existing conditions are provided throughout the EIR and, in particular, conditions for each environmental issue are presented in the section addressing that topic. For example, Section 4.5 (Agricultural and Forestry Resources) provides information on existing Farmland designations, mapped Agricultural Preserve locations and lands designated AG LUD in the General Plan, etc., within Riverside County. These baseline conditions apply to both the incorporated and unincorporated portions of Riverside County. See Table 6.4-E (Agriculture Emphasis Alternative – Assumptions and Projections) for the full baseline data set used for this alternative. See the footnotes to this table for additional comments on the baseline assumptions.

Table 6.4-E: Agriculture Emphasis Alternative – Assumptions and Projections

Agricultural Emphasis Alternative ASSUMPTIONS [7]	Baseline: Existing (2007) Conditions [1, 3]			Build out: Future (2060) Conditions [2, 4, 6]		
	Unincorp. County	Cities [5]	Countywide Total	Unincorp. County	Cities [5]	Countywide Total
Land Uses						
Residential	109,600 ac	113,700 ac	**223,300 ac**	470,700 ac	186,100 ac	**656,800 ac**

Footnotes:
1. Source for land use, existing: EIR Table 4.2-F.
2. Source for land use, build out: Modeled for alternative (Unincorporated County) and estimated from RCCDR 2012 data for "Cities, Build out."
3. Source for socioeconomics, existing: EIR Table 4.3-G.
4. Source for socioeconomics, build out: EIR Table 4.3-G for the cities and modeled for alternative (Unincorporated County).
5. Since their incorporations occurred after the date of NOP issuance for this EIR, the cities of Eastvale and Jurupa Valley are included in the unincorporated baseline county totals, rather than the incorporated totals.
6. "Build out" conditions are those projected for full realization of the alternative's land use plans. For this alternative, the build out scenario includes the following assumptions:
   a. All development within the unincorporated portion of Riverside County occurs as directed by the existing (2008) Riverside County General Plan. No additional unincorporated lands are annexed into any cities.
   b. The incorporated portions of Riverside County fully develop (build out) according to the land uses mapped in the existing General Plans for the individual cities (as interpreted by RCCDR).
7. All values rounded to the nearest hundred. Thus, totals may not sum precisely.
8. Commercial uses include commercial-retail, commercial-office, commercial-tourist, community center and MUPA (mixed-use).
9. Industrial uses include heavy and light industry, business parks, warehouses and public facilities, as well as mining and (active) recreational uses.
10. Open space uses include conservation lands, as well as water (lakes, etc.).
11. "Other" uses encompass any not listed elsewhere and include freeways, roads, canals, etc., as well as vacant (undeveloped) lands.

Source: See footnotes, above, for data sources.

b. Build Out Assumptions

For this particular alternative, it is assumed that no other changes to the General Plan are made and that the unincorporated portions of Riverside County build out as directed by the existing General Plan. The assumptions and land use changes described above were then applied, resulting in a build out scenario specific to the Agricultural Emphasis Alternative. See Table 6.4-E, above.

2. Environmental Implications

Pursuant to Section 15126.6(d) of the State CEQA Guidelines, Table 6.4-F (Agricultural Emphasis Alternative – Environmental Effects Summary), below, outlines in matrix form the significant environmental effects of the Agricultural Emphasis Alternative. A discussion of the alternative's significant environmental effects follows. Where the alternative would cause a significant effect beyond that of the proposed project, it is discussed below.

Table 6.4-F: Agricultural Emphasis Alternative – Environmental Effects Summary

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
4.2 – Land Use							
4.2.A	Physically divide an established community.		•				=
4.2.B	Conflict with land use policies intended to avoid or mitigate an environmental effect.		•				↓
4.2.C	Conflict with any habitat conservation plan or natural community conservation plan.		•				↓
4.3 – Population and Housing							
4.3.A	Induce direct or indirect population growth.					◊	↑
4.3.B	Displace residential units.		•				↓
4.3.C	Displace people.		•				↓
4.4 – Aesthetic and Visual Resources							
4.4.A	Adversely affect scenic vistas.			•		•	↓
4.4.B	Adversely affect scenic resources within State Scenic Highways.			•			↓
4.4.C	Adversely affect existing visual character.			•			↓
4.4.D	Cause adverse light and glare effects.		•			•	↓
4.4.E	Interfere with nighttime use of the Palomar Astronomical Observatory.		•				↓
4.5 – Agricultural and Forestry Resources							
4.5.A	Cause the direct or indirect conversion of designated Farmlands.		•				↓
4.5.B	Encroach on or conflict with existing agricultural uses.		•				↓
4.5.C	Adversely affect forest lands and forestry uses.		•				↓
4.6 – Air Quality							
4.6.A	Conflict with air quality plans.			•	•	•	↑
4.6.B (1)	Cause significant construction (short-term) air emissions.				•	•	↑
4.6.B (2)	Cause significant operational (long-term) air emissions.				•	•	↑
4.6.C	Cause cumulatively significant project air quality impacts.				•	•	↑
4.6.D	Expose sensitive receptors to air pollutants.				•	•	↑
4.6.E	Expose substantial numbers of people to objectionable odors.			•			↑

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul . Significant	Relative to Proj.[4]
4.7 – Greenhouse Gases							
4.7.A	Generate substantial greenhouse gas emissions.			•		◊	↑
4.7.B	Conflict with greenhouse gas reduction plans, policies or regulations.			•		•	↑
4.8 – Biological Resources							
4.8.A	Adversely affect riparian or other sensitive habitats.			•			↓
4.8.B	Cause direct and indirect impacts to protected species or their habitats.			•			↓
4.8.C	Adversely affect wetlands.			•			↓
4.8.D	Impede species movement, migration, wildlife corridors or use of wildlife nursery sites.			•			↓
4.8.E	Conflict with adopted habitat conservation plans.		•				↓
4.8.F	Conflict with local biological resource protection policies or ordinances.		•				↓
4.9 – Cultural and Paleontological Resources							
4.9.A	Adversely change the significance of historical resources.		•				↓
4.9.B	Cause the destruction of known archeological resources.			•			↓
4.9.C	Cause the destruction of unique paleontological resources or sites.		•				↓
4.9.D	Result in the disturbance of human remains.		•				↓
4.10 – Energy Resources							
4.10.A	Increase demand for electricity.		•			◊	↑
4.10.B	Increase demand for natural gas.		•			◊	↑
4.10.C	Cause the inefficient use of energy.		•				↓
4.11 – Flood and Dam Inundation Hazards							
4.11.A	Result in housing within flood hazard areas.		•				↑
4.11.B	Cause impediment of flows.		•				↑
4.11.C	Expose people or structures to flooding hazards, including flooding due to dam or levee failure.		•				↑
4.11.D	Cause the adverse alteration of drainage patterns or substantially increase surface runoff.		•				↓
4.11.E	Cause inundation risks due to seiche, tsunami or mudflow.		•				↑
4.12 – Geology and Soils							
4.12.A	Expose people or structures to substantial adverse effects due to rupture or a known earthquake fault.		•				↑
4.12.B	Expose people or structures to substantial strong seismic groundshaking.		•			•	↑
4.12.C	Expose people or structures to substantial adverse effects due to seismic-related ground failure, including liquefaction.		•				↑
4.12.D	Expose people or structures to substantial adverse effects due to landslide.		•			•	↓
4.12.E	Result in substantial soil erosion or topsoil loss.						↓
4.12.F	Result in development on unstable geological units or soils.		•				↓
4.12.G	Result in development on expansive soil.		•				↓
4.12.H	Result in development on soils incapable of supporting septic tanks or alternative wastewater disposal systems.		•				↓
4.13 – Hazardous Materials and Safety							
4.13.A	Create a significant hazard through the routine transport, use or disposal of hazardous materials.		•				↑

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul . Significant	Relative to Proj.[4]
4.13.B	Cause a significant hazard through the accidental release of hazardous materials.		•				↑
4.13.C	Result in hazardous emissions or related hazards within ¼-mile of a school.		•				↑
4.13.D	Result in a significant hazard due to development on a Cortese List hazardous materials site.		•				↑↓
4.13.E	Result in a safety hazard for people within a two-mile radius of a public or public use airport.		•				↑
4.13.F	Result in a safety hazard in the vicinity of a private airstrip or heliport.		•				↑
4.13.G	Impair or interfere with adopted emergency response or evacuation plans.		•				↓
4.13.H	Expose people or structures to significant risk due to wildland fire.		•				↓
4.14 – Mineral Resources							
4.14.A	Result in the loss of availability of delineated locally important minerals.	•					=
4.14.B	Result in the loss of availability of known mineral resources.		•				↓
4.15 – Noise							
4.15.A	Generate noise or cause noise exposure in excess of standards.				•	•	↓
4.15.B	Generate or cause exposure to excessive groundborne vibration.			•			↓
4.15.C	Result in a substantial permanent increase in ambient noise levels.				•	•	↓
4.15.D	Result in a substantial temporary or periodic increase in ambient noise.				•	•	↓
4.15.E	Expose people to excessive airport-related noise levels.		•				↓
4.16 – Parks and Recreation							
4.16.A	Increase the use of existing parks or recreational facilities resulting in their substantial physical deterioration.		•			•	↑
4.16.B	Trigger growth effects resulting in the need for additional parks or recreational facilities.		•				↑

Footnotes:

1. Impacts are based on a comparison of the effects of build out of the alternative as compared to the environmental baseline. Unless noted otherwise in the text, the environmental baseline is assumed to be the same as or substantially similar to that described for the proposed project in Sections 4.0 through 5.0 of the EIR.
2. Only impacts requiring new CEQA-specific mitigation measures to reduce their impacts to less than significant are considered to be "less than significant with mitigation." (Compliance with existing laws, ordinances, regulations, etc., is assumed under CEQA.)
3. Diamond (◊) denotes an impact that is substantially greater than for the General Plan as updated per GPA No. 960.
4. Severity of projected impacts relative to proposed project (rather than environmental baseline), for comparison purposes: ↓, less severe; ↑, more severe; ↓↑ = areas of each result; and, **=** , approximately the same.
5. Shaded yellow boxes denote impact finding for build out of the General Plan with GPA No. 960 (per Table 5.5-AJ) for comparison.
6. Note: Decrease only applies to vehicle trips on public roads, not off-road operations associated with agricultural uses.

Source: Riverside County Planning Dept., new analysis and results from EIR Sections 4.2 - 4.19 and 5.1 - 5.5, 2012.

Overall, the shifting of open space-rural land uses to agriculture and conserved open proposed under this alternative serves a number of complimentary purposes. Even though open space conservation is increased greatly, with the increase in agricultural uses, this alternative would yield an increase of nearly 9,000 dwelling units and over 44,000 jobs, plus a population increase of 19,000 people as compared to build out under the updated General Plan. It does so by expanding the agricultural footprint of Riverside County and slightly increasing the average densities of the developed (urban and suburban) portions of unincorporated Riverside County. (From an average density of 1.8 to 2.0 du/ac for single-family residential uses and from 8.3 to 8.7 du/ac for multi-family residential.) The restriction on Agriculture Foundation conversion would focus suburban and urban development in areas mapped and already planned for such uses, both within Riverside County unincorporated areas as well as in cities.

As shown in Table 6.4-F, this alternative would have a number of significant environmental effects (either individual, in localized areas or cumulative). Certain of these significant environmental effects would be substantially worse than those associated with the project-updated General Plan. These effects, which are discussed further below, include:

- Induce direct or indirect population growth (within the urban areas benefitting from rural density transfers).
- Increase greenhouse gas emissions.
- Increase demand for energy (electricity and natural gas).
- Increase demand for water supplies, both imported and groundwater.
- Cause significant environmental impacts due to the construction of additional infrastructure needed to harvest and/or deliver additional water to meet demand.

a. General Impacts

Overall, as indicated in Table 6.4-F, the Agricultural Emphasis Alternative would generally have environmental effects similar to, but slightly (2-8%) greater than, the proposed project's within the urban and suburban portions of Riverside County because of the slight increase in housing, jobs and population that this alternative would realize from the increased densities and agricultural uses. Despite these increases, the elimination of the OS-RUR land use with 80% reallocated as OS-C would result in a county development footprint that is over a million acres (over 1,500 square miles) smaller than currently proposed.

Thus, in general, when compared to the environmental impacts associated with build out of the existing General Plan, this alternative would have substantially fewer significant environmental impacts related to spatial effects within the Riverside County development footprint. These include reductions in impacts to: aesthetic and visual resources, biological resources, cultural resources, mineral resources and floodplains, hydrology, geology and, of course, agriculture. In particular, the decreased footprint would result in a substantial reduction in wildland fire risks and substantially less encroachment into isolated and remote areas.

Conversely, with the density and intensity increases within urban and suburban areas, this alternative would have slightly increased population-driven impacts, including: air quality, water and energy demand, exposure to seismic and geologic risks, exposure to hazardous materials and demands for various public services and facilities, including law enforcement services, wastewater treatment, schools, libraries and medical services, as well as parks and recreational opportunities. None of these population-based increases would be substantially greater than

those predicted for the proposed project, however. Key items related to these impacts are discussed more fully below.

b. Agricultural Resource Impacts

Under this alternative, agricultural uses would continue and prosper throughout Riverside County. This alternative proposes for agricultural-designated land use to more than double compared to existing plans and the conversion of agricultural lands to non-agricultural uses would be halted or substantially limited. The existing General Plan has 189,700 acres designated as agriculture (i.e., AG LUD) and the General Plan, as updated pursuant to GPA No. 960, would have 188,900 acres designated AG. SCAG data on existing uses of land, however, reflect a total of roughly 226,900 acres of agricultural uses currently within unincorporated Riverside County. Thus, build out of either scenario would result in a loss of 37,200 acres (existing General Plan) to 38,000 acres (updated General Plan). The 441,400 acres proposed under this alternative would more than ensure that no existing agricultural uses need be lost to development.

Under this alternative, the rate of conversion, amount, extent and distribution of development in and around agricultural areas would be greatly reduced outside of the ECVAP area. Agricultural conversion would still be permitted quarterly in the eastern Coachella Valley region, but with the 50% easement requirement, based on existing agriculture designations, at least 23,000 acres of agricultural lands would remain protected.

Overall, by limiting and slowing the introduction of new development in close proximity to existing agricultural operations, this alternative would also greatly reduce the effects of potential land use incompatibility and the effects of urban/suburban encroachment into agricultural areas. While some nuisance impacts associated with agricultural operations (e.g., noise, dust, odors) would still occur, the homogenous nature and broad dispersal pattern of the agricultural areas, when compared to the existing General Plan or the proposed project, would ensure such impacts are less than significant.

c. Housing Impacts

California's Housing Element law requires that each city and county develop local housing programs designed to meet its "fair share" of housing needs for all income groups, as determined by the jurisdiction's Council of Governments, when preparing the state-mandated Housing Element of its General Plan. This fair-share allocation concept seeks to ensure that each jurisdiction accepts responsibility for the housing needs of not only its current population, but also for those households who might reasonably be expected to reside within the jurisdiction, particularly lower-income households. Overall the County of Riverside was able to meet the majority of its quantified objectives for the 1998-2005 planning period per the General Plan Housing Element. However, with respect to units for very low, low and moderate income families, additional homes are needed in Riverside County per RHNA targets. Although the County of Riverside did produce over 12,500 units, it was almost 6,000 units short of the RHNA targets in these three categories.

The RHNA allocation for Riverside County for the subsequent eight and a half-year planning period as approved by SCAG in July 2007 represents an increase of approximately 26,500 units over the prior (1998-2005) RHNA period. Evaluation of residential-designated vacant lands under the existing General Plan finds that RHNA targets would be met within both the western and eastern portions of Riverside County, with the exception of the Low Income target in the western county, which would be 1,300 dwelling units short. The available land analysis does not formulate dependence on agricultural land use designation conversions to meet future housing needs. Additional land use conversion to accommodate the projected deficit may occur in the western county, resulting in pockets of higher densities development.

Under this alternative, the reallocation of densities includes over 17,000 du of multi-family residential LUDs. With their higher densities, these categories are particularly well-suited for addressing low-income housing needs. Thus, this alternative would be a substantial improvement over the existing General Plan in terms of enabling low-income housing availability.

d. Biological Impacts

Within Community Development Foundation areas, impacts associated with this alternative would be slightly higher due to the slightly increased densities. Existing mitigation, such as compliance with the requirements of the WR-MSHCP and CV-MSHCP, would ensure that biological impacts associated with this alternative were less than significant. Even though less than significant, however, this alternative would result in a substantial reduction in the extent of biological impacts due to the million-plus acre reduction in the overall size of the development footprint within Riverside County. With 1,003,500 acres shifting from rural residential (OS-RUR) to conservation (OS-C) under this alternative, the effects of human encroachment, edge effects, habitat disturbance and similar effects would be greatly reduced. As such, this alternative would have less impacts to biological resources than either the existing General Plan or the proposed project.

e. Wildfire and Fire Protection Impacts

For reasons similar to that of biology, this alternative would also provide a substantial reduction in cumulative wildfire risks and, hence, demands on fire protection services. Under the existing General Plan, over 50,000 homes would be possible scattered throughout the million-plus acres of existing OS-RUR lands. Diffuse rural residential development in remote and isolated areas us the type of development pattern most vulnerable to wildland fires. These residences are also the most problematic for fire protective services to defend, given their remote locations, unimproved (dirt) access roads and lack of readily-accessible water supplies. By reallocating 50,000-plus homes from the most rural areas of Riverside County and reducing the overall development footprint by over a million acres (1,500-plus square miles), the potential for people, structures and property to be put at risk for wildland fires is greatly reduced under this alternative compared to that of either the existing General Plan or the proposed project.

f. Air Quality Impacts

As described more fully under for the Added Community Centers Alternative (Section 6.4.D, below), simulations (modeling) were run for various alternative scenarios in order to elucidate the effects of the various competing factors influencing air quality and greenhouse gas emissions, as well as traffic. Towards this end, several land use simulations were developed and modeled via the South Coast Air Quality Management District's (SCAQMD's) CalEEMod software. Results of the modeling indicate that this alternative would result in increased operational air pollutant emissions (for example, ROG, NOx and total PM-10), despite a projected decrease in VMTs. This increase occurs despite the VMT decrease because, while the number of miles traveled on public roads, such as freeways and arterials, would decrease, the number of miles traveled off-road (that is on the farmlands themselves) in association with the increased agricultural uses would increase (e.g., taking into account operation motorized farm equipment, such as tractors, threshers, trucks, etc.). Thus, air pollutant emissions would increase, even though the traffic volumes on public roads would decrease. In addition, the increased number of homes and employment sources (agricultural, as well as related commercial and industrial uses) would also contribute to increased air quality pollutant emissions.

Although increased, however, analysis indicates this alternative's air quality impacts would be generally similar to, if somewhat greater than, those associated with build out of either the existing or updated General Plan. For

build out of the existing General Plan, EIR No. 441 found there would be several significant and unavoidable air quality impacts, even after the implementation of all feasible mitigation. Significant short-term air quality emissions, particularly of fugitive dust (PM_{10}), would occur during construction activities, such as site preparation, as well as seasonally during specific agricultural activities, such as disking or plowing, for example. Likewise, significant long-term air pollutant emissions would occur from stationary sources within Riverside County in cumulatively-significant, if not individually significant, levels that exceed applicable air quality standards. For this alternative, such impacts would be substantially the same.

In addition, these significant emissions would also collectively result in the exposure of sensitive receptors (including children, the elderly and the infirm) to substantial air pollutants, particularly where increased densities under this alternative would increase the number of people within close proximity (500 feet or less) to freeways and other high-volume traffic sources, warehouses and other industrial uses associated with high diesel and other particulate emissions. Both the alternative and the existing General Plan build out scenarios, in addition to that of the proposed project, would result in significant impacts. Lastly, within the rural agricultural areas, it is possible that fugitive dust impacts would be greater since dust generation is a common hazard associated with land cultivation (disking, plowing, planting, harvesting, etc.) and the amount of agricultural lands would more than double under this alternative.

g. Greenhouse Gas Impacts

As with air pollutants, this alternative would generate slightly more GHG emissions than the proposed project due to the associated small increase in development potential, population, jobs and vehicle operations, particularly off road. As a result of these increases, CalEEMod simulations indicate that GHG emissions would also increase if no actions are taken to mitigate them. Since the existing General Plan was originally adopted prior to the establishment of the various GHG reduction policies, programs and goals in California, it does not currently address the issue. However, the assumption that a Riverside County CAP of some sort would be adopted as part of this alternative resolves this issue and that GHG reduction measures would be implemented. However, because off-road vehicle operations are difficult to reduce through traditional means (e.g., increasing use of carpools, mass transit, bicycles, etc.), it is unlikely that significant GHG emissions could be reduced to less-than-significant levels under this alternative. Therefore, this alternative would likely result in significant GHG emissions above those projected for project-updated General Plan build out.

Pursuant to AB 32, the State of California issued a Scoping Plan outlining measures to achieve greenhouse gas reduction targets. A key focus of reduction plans is centralizing development impacts within urban areas as a means for reducing VMT. Thus, even with the additional emissions associated with off-road (i.e., agricultural) equipment and vehicle operations, associated GHG emissions would be offset, at least in part, by the savings derived from the higher urban/suburban residential densities also proposed. By reducing the overall development footprint of unincorporated Riverside County by over a million acres and reallocating 50,000-plus homes into more urban/suburban areas, this alternative would further the VMT reduction goals established by SCAG pursuant to SB 375 and, therefore, AB 32 GHG reduction goals would be advanced as well.

h. Energy Impacts

The increased number of homes associated with this alternative would generally result in greater demand for connection to existing infrastructure (particularly for electricity and natural gas)

However, the smaller residential units (particularly multi-family homes) facilitated by this alternative generally achieve better energy efficiency and improved energy conservation than compared to the larger rural homes that

would be facilitated under the existing General Plan and proposed project. Attached unit, for example multi-family apartment buildings, are associated with greater energy and water savings. The improved energy efficiency of this alternative would, however, be offset by the increased amount of electricity necessary to provide sufficient water supplies to serve the increased agricultural and economic uses proposed. (Assuming such water imports are even available; see water supply discussion, below.) Water use in California consumes significant amounts of energy and agricultural uses rely heavily on water supply. Research by the California Energy Commission (CEC) indicates that overall, water-related energy needs consumed 19% of all of California's electricity used in 2001 (roughly 48,000 GWh out of 250,500 GWh total). This included over 10,500 GWh dedicated to agricultural water supply and end use. (See page 5 of the CEC's report, "California's Water-Energy Relationship," (CEC-700-2005-11-SF), 2005.)

However, even though agricultural water use encompasses roughly 80% of all water used in the state, agricultural uses account for only 30% of all water supply and treatment needs; the other 70% is used by urban water users (residential, commercial and industrial uses). On-farm agricultural water use consumes an additional 15% of water-related electricity. Water for urban uses requires additional energy input to meet regulatory standards for consumption. By emphasizing agricultural uses, this alternative would increase (up to nearly double) the amount of electricity required for water-related uses. Overall, demand for agricultural water, combined with the increase in homes and employment uses, means that incremental increases in electricity demand would be cumulatively significant for this alternative.

Lastly, urban water uses (particularly water heating for homes and businesses, as well as industrial boilers) account for nearly all (99.5%) natural gas use. Thus, the increase in residential units proposed under this alternative would result in an increase in natural gas demand as well. Though substantial, none of these significant energy impacts are new, however, since demand for electricity and natural gas was already projected to be cumulatively significant at General Plan build out with GPA No. 960.

i. Traffic and Circulation Impacts

Under this alternative, a greater proportion of Riverside County's expected population growth would be accommodated in urban areas, instead of rural, wildland and interface areas, as a result of the density transfers proposed. By moving people into areas of higher residential densities and associated economic uses (retail, commercial, industrial, etc.), the total VMT on public roads, such as freeways, county arterials, etc., can be decreased as needed services, jobs and other trip destinations are located closer. In addition, these trips would be concentrated into an area roughly 1,500 square miles smaller than under the existing General Plan or the proposed project. Accordingly, for this alternative, the CalEEMod simulation run indicated decreased VMTs, despite the increased number of residents and workers. The increased densities and intensities in the urban centers would also have beneficial effects on non-vehicular transportation; making pedestrian travel, bicycle and mass transit use more amenable to the public.

In terms of roadways, a smaller VMT increase means traffic congestion would be less severe at build out. Fewer improvements would be needed for the freeway and local roadway networks to ensure adequate levels of service (LOS) are maintained along the networks' roadway segments and intersections. In areas where existing roadway capacities are already functioning at unacceptable levels, additional increases in traffic would occur more slowly, delaying the incremental contributions to cumulatively significant congestion levels. In total, although this alternative would reduce traffic impacts, as compared to project-updated General Plan build out, these impacts would still be both individually (for specific road segments and intersection) significant and cumulatively considerable. They would not, however, be substantially higher than levels forecast for build out of either the existing or project-updated General Plans. These are not new substantial impacts, however, since traffic impacts were already projected to be significant, both individually and cumulatively, at build out for GPA No. 960.

Despite lower on-road miles travel, this alternative would also increase the number of off-road miles traveled in association with the increase in agricultural uses. As noted under the air quality discussion above, even though these increases affect air pollution and GHG levels, they do not greatly affect vehicle traffic on public roads; agricultural vehicles and equipment are operated primarily on farmlands. Truck traffic on public roads may, however, increase as the amount of produce and other agricultural products shipped out of Riverside County increases. Again, these increases are offset by decreases in other (i.e., urban) VMTs. In conjunction with the agricultural traffic increases, adverse effects associated with incompatible uses (i.e., Impact 4.18.E) would also increase, although not to levels substantially higher than those projected for project-updated General Plan build out.

All other transportation-related impacts associated with this alternative would be substantially the same as those for the existing General Plan and the proposed project, except in two areas. Because of the million-plus acre reduction in rural development footprint, emergency access impacts would be less substantial under this alternative. Roughly 50,000 fewer homes would be built in rural, remote or isolated areas in which emergency vehicles access would be difficult and emergency evacuation, for example in the event of a wildfire, would be perilous. Both this alternative and the proposed project would have less-than-significant effects in this area. Secondly, in terms of public transit and non-motorized travel, the slight increase in housing density proposed under this alternative would also slightly lower the already insignificant impacts of the proposed project. Also, the smaller development footprint also makes transit, walking and other alternate forms of transportation more viable within a community.

j. Noise Impacts

Since motor vehicle travel is the largest single source of noise generation in Riverside County, keeping VMTs from rising directly affects (decreases) the build out noise levels for receptors along roadways. Thus, the lower total on-road VMTs predicted for this alternate (as compared to project-updated General Plan build out), would result in fewer significant noise impacts within Riverside County. Although not new, this alternative would nevertheless have some impacts that would be individually (locally) significant or cumulatively considerable.

In some locations existing (baseline) noise levels already exceed acceptable standards. As such, the VMT resulting from this alternative, particularly from agricultural vehicles increasing off-road noise levels, would further exacerbate such impacts. Agricultural equipment noises tend to be occasional or periodic, for example used only during harvest or for sowing new crops, etc., and thus do not significantly affect long-term ambient noise levels in most areas. However, due to the widespread, incremental nature of traffic-related noise increases, it is not possible to avoid or mitigate all significant ambient noise impacts to the thousands of homes and other uses that would ultimately be exposed to excessive noise levels over time. Thus, future increases in (long-term) ambient noise, as well as short-term (construction or agricultural) noise, exceeding standards would be cumulatively significant under this alternative. These significant noise impacts, however, would be substantially similar in scale to those forecast for build out pursuant to GPA No. 960; they do not represent new substantial impacts associated with this alternative.

Where lands designated for rural residential (OS-RUR) would be reallocated to conserved open space (OS-C), noise impacts would be reduced because fewer homes would be built in the rural, remote and isolated portions of Riverside County. In these areas, noise levels are generally already low, but because of the natural quietness of these areas, even small additional noise sources can be bothersome. Thus, the reduced development in these areas would be very beneficial to lowering noise levels contributing to biological "edge" effects and other issues affecting the suitability of open space for wildlife use.

k. Public Facilities, Parks and Recreation Impacts

As with other population-based effects, the slight (2%) increase in population that would be accommodated by this alternative would result in slightly higher impacts to parks and recreational facilities and other public facilities (including schools, libraries, landfills, medical facilities, government facilities, etc.) Among other things, this would also increase the effects of use (e.g., wear and tear) on existing parks, recreational and other public facilities, as well as increase the need for additional facilities to serve the growing populace. As with the existing General Plan, this alternative would also result in a number of significant cumulative effects on public facilities as well; as shown in Table 6.4-F.

l. Water Impacts

Under this alternative, lands designated as agricultural (AG LUD) would more than double, from 189,700 acres in the existing General Plan to over 441,000 acres, and the rate of allowed agricultural conversions, i.e., redesignating agricultural lands to non-agricultural uses, would be greatly reduced (allowed once every eight years rather than four times a year). This would help protect the roughly 227,000 acres of current agricultural uses within unincorporated Riverside County at present and encourage the expansion accommodated under this alternative. This expansion would substantially increase the need for irrigation water, roughly doubling demand for agricultural water alone.

Increased agricultural demand would be slightly (approximately 1,000 acre-feet per year) offset by the 1.2 million acres removed from Riverside County's residential development footprint. The increase in higher-density urban homes replacing large-lot rural and estate density residences (which typically use much more water) would reduce the overall amount of domestic (potable) water demand and also decrease the amount of water used for residential landscape irrigation. Wastewater generation would also be lower.

Since California's water supply is finite and the State of California has identified critical constraints related to imported water availability, the increased water demand associated with this alternative would substantially increase environmental impacts to water resources, particularly to supply necessary agricultural water (which may be non-potable); in particular, build out of Riverside County pursuant to this alternative would result in cumulatively significant impacts on imported and local water supplies. In addition to using water for irrigation, use of water would also increase for related agricultural and industrial activities, such as watering livestock, producing milk (i.e., dairy use) and food processing (washing, etc.). Further, if the cost for imported water continues to increase (particularly due to increasing scarcity and continuing increases in electricity costs; see energy discussion), this could have be a severely limiting factor in the economic viability of continued agricultural production within Riverside County. With demand increasing greatly, there would also be the potential for significant environmental impacts to occur as a result of the construction of additional infrastructure needed to harvest, treat and deliver additional water, or recycle or otherwise reclaim existing water.

In terms of other water impacts, fewer homes built in areas outside of water agency service areas would mean decreased reliance on local groundwater. Additionally, the decreased housing total in rural wildland and interface areas would mean fewer homes being built where no sanitary sewer connections are available. Frequently homes in remote and isolated areas must rely on individual septic systems or other private subsurface wastewater disposal facilities, which can cause potential water quality impacts and other adverse environmental effects. Thus, by reducing the total number of homes of this type, this alternative would have fewer impacts on water quality resulting from septic systems.

Lastly, the smaller overall development footprint within Riverside County resulting from the reduction in rural and interface residential development under this alternative would also help ensure that a number of other water-

related impacts of this alternative are less severe than that of the proposed project or the existing General Plan. These include: water quality degradation, potential violations of water quality standards, changes in drainage patterns and increased erosion, and lastly, increased runoff of stormwater.

m. Significant Cumulative Impacts

In general, most of the impacts found cumulatively significant for this alternative are substantially similar to those predicted for the proposed project. However, there are a few exceptions: First and foremost, as mentioned above, this alternative would avoid both the individually and cumulatively significant agricultural impacts associated with build out of either the existing General Plan or the proposed project. With its greatly reduced rural development footprint, it would also avoid cumulatively significant impacts to archeological and paleontological resources. Cumulative wildfire hazards (particularly in interface and wildland areas) would be less than significant, as would demands for fire protection services. The smaller development footprint means cumulative effects on existing hydrology and stormwater drainage systems would also be less than significant. This alternative would also avoid significant growth-inducing effects due to encroachment of new development into isolated or remote areas.

However, the greatly increased water demand could potentially result in other new substantial environmental impacts as a result of the development of new water-harvesting facilities (e.g., reservoirs) and other water infrastructure. Lastly, the increased demand for energy (electricity and natural gas) due mainly to increased agricultural uses, such as water pumping, and related economic uses (commercial, industrial, etc.) would result in cumulatively significant energy impacts. See the energy discussion, above. Thus, for these reasons, this alternative's cumulative effects on water resources and groundwater basins due to increasing demand would be substantially higher than that projected for project-updated General Plan build out.

n. Growth Inducement

With its slightly larger urban development potential and slightly smaller rural residential footprint, the Agricultural Emphasis Alternative would accommodate a slightly higher number of homes, population and workforce than the proposed project. As such, this alternative's growth-inducing effects would also be slightly higher than those of the project. Akin to those of the project, most of this alternative's growth-inducing impacts would be significant and unavoidable. This alternative would foster direct and indirect population growth and economic growth. It would also facilitate the construction of additional housing. It does not, however, address (update) existing Rural Village Study Areas (RVSAs) or Rural Village Overlays. As such, this alternative would not remove the obstacles growth that have arisen in the existing General Plan due to lack of detailed planning for the RVSAs. And, in fact, by requiring an eight-year window for all Agriculture Foundation LUD changes (except those within ECVAP), this alternative would actually create additional growth inhibitions within Riverside County. For these reasons, growth inducement Impact 5.4.E was found to be less than significant.

o. Impacts to Cities

The proposed alternative is derived from build out of the existing Riverside County General Plan, with modifications, thus impacts to cities were not included in Table 6.4-F. Rather, it was assumed that growth within the cities would occur in accordance with each city's general plan, as required by state law. See Table 6.4-C for RCCDR estimated build out results for incorporated Riverside County.

Though not addressed separately, the significant effects of this alternative on the cities within and adjacent to unincorporated Riverside County would be limited principally to cumulative effects caused by the incremental

contributions arising from development in the county. These significant cumulative effects would occur in areas where additional future county development causes an impact to exceed a threshold or standard of acceptability. This would occur where development in unincorporated Riverside County areas borders city areas or causes traffic, noise or other effects that carried over the municipal boundary.

In addition, the limit on agricultural conversion within unincorporated areas may also serve to drive more development into the cities as well. This would serve to increase the cumulative effects within the cities as a result. Significant cumulative effects to cities result from this alternative would include:

- Affects to scenic vistas and existing visual character within cities.
- Encroachment on or conflicts with existing agricultural uses within cities.
- Air quality effects where emissions occurring within Riverside County would affect air pollutant levels within cities, including for short-term (construction) and long-term (operational) emissions, particularly traffic-related emissions. Exposure of sensitive receptors within cities to air pollutants generated within Riverside County and cumulatively significant air quality impacts could also occur.
- Greenhouse gas emissions (to the extent that traffic generated by activities within unincorporated Riverside County affected trips and congestion within cities).
- Noise level increases within Riverside County could affect levels within cities, including for construction (short-term) and operational (long-term) emissions. In particular, traffic-related noise increases could result in cities as a result of changes in county traffic patterns and/or increased trips.
- Increased traffic within Riverside County would also result in significant traffic increases in cities where links between city and county circulation networks interface. That is, increased traffic could affect cities in two ways: First, by causing traffic slowing on county roads which would lead to slowing or backups on city roads. Second, when a county roadway becomes less able to accommodate traffic, drivers seeking alternate routes may end up traveling through cities on surface streets. Lastly, development of land uses that attract visitors (such as regional shopping malls, medical centers, universities, casinos and other large-scale uses) within unincorporated Riverside County could increase trips on city roads that lead to/ link to the use within Riverside County.
- In locations where cities rely upon the same groundwater basin(s) that also serve an unincorporated area, additional development within Riverside County could lead to significant demands on the city's existing water supply. Where a groundwater basin is already in overdraft or adjudicated, or where future demands would exceed the recharge capability of the basin, both the city and county areas relying on the basin would be significantly affected. This may particularly be significant where additional agricultural demands would be met solely by groundwater from basins shared by city water providers.
- Where cities and unincorporated areas are both served by the same water district, additional development within Riverside County could increase demand on the existing imported water supply. Since such supplies are finite and subject to factors beyond the control of the water district (e.g., rainfall amounts, state mandates, court-ordered diversions for fish species in the Sacramento/San Joaquin Delta, etc.), increases exceeding the districts' ability to meet the need would result in significant impacts.

3. Achievement of Project Objectives

In terms of the project's stated objectives, this alternative does not satisfy several: It would not provide a suitable plan for further progress within Riverside County since it does not update the study areas identified in 2003 for future planning specifications. It does not include any LUD updates and thus does not address the updated land use objective. It would provide updated technical data, simply by definition. It also would address the updated regulatory environment that future development within Riverside County would need to comply with (e.g., AB 32 and greenhouse gas reduction planning) for similar reasons. It would not, however, fully comply with AB 32 due to the substantial increase in greenhouse gas emissions associated with this alternative. Nevertheless, in all, this alternative could be said to adequately meet the address new needs objective. It does not, however, further the Riverside County Vision in regards to growth since the restrictions on agricultural conversion would significantly hinder (not "enhance" or "extend") "continued progress" within Riverside County.

4. Conclusions

Overall, as indicated in Table 6.4-E, the Agricultural Emphasis Alternative would cause slightly more significant environmental impacts in the growing urban and suburban portions of unincorporated Riverside County, while substantially reducing many (but not all) impacts associated with spatial effects in the rural portions of Riverside County. In several key areas, this alternative would avoid, minimize or reduce impacts found significant under the proposed project to less-than-significant levels. These include: conversion of state-designated farmlands and encroachment or conflicts with existing agricultural uses; exposure of people or structures to wildland fire risks; and, facilitation of environmental effects due to the encroachment of development into isolated or remote areas.

With its greatly reduced rural development footprint, it would also avoid cumulatively significant cumulative impacts to archeological and paleontological resources, hazards (particularly in interface and wildland areas), demand for fire protection services and effects on water resources and groundwater basins. The smaller development footprint means cumulative effects on existing hydrology and stormwater drainage systems would also be less than significant. This alternative would also avoid significant growth-inducing effects resulting from facilitating encroachment into isolated or remote areas. However, because this alternative restricts agricultural conversion, it would hinder (reduce) significant growth-inducing effects by creating (rather than removing) obstacles to population growth within Riverside County.

Lastly, this alternative would also result in several substantially greater (worse) environmental impacts, including: greatly increased demand for water, both imported and local (groundwater); increased demand for energy (electricity and natural gas) due mainly to increased agricultural uses (particularly water pumping) and related economic uses (dairies, commercial, industrial, etc.); and, increased energy use and increased off-road equipment and vehicle operations associated with agricultural uses, contributing to substantial cumulative greenhouse gas emissions. And, lastly, environmental impacts associated with the need for new or expanded water infrastructure. Except for the greenhouse gas emissions, however, none of these cumulatively significant impacts are new as compared to those of the project-updated General Plan.

Taken together, this alternative adequately addresses four of the seven areas of significant effects associated with the proposed project, including having substantial improvements over the project in terms of both agricultural impacts and on-road vehicle traffic levels. It would also, however, be associated with three areas of more severe, environmental impacts, including increased water demand and increased cumulative impacts in several areas. Although an improvement over the project in some ways, this alternative would not be the environmentally superior alternative due to the severe limitations and significant environmental impacts that would result in

conjunction with the greatly increased water demand under this alternative. For these reasons, this alternative was not deemed the environmentally superior alternative.

Further, as outlined above, this alternative only meets two of five of the objectives of the project. Thus, this alternative is not an acceptable means for achieving the stated project objectives. For all of these reasons, the Agricultural Emphasis Alternative is not deemed the preferred alternative.

D. Added Community Centers Alternative

Sprawling patterns of suburban growth in car-centric Southern California tend to result in increased traffic, noise and air pollution as vehicle travel increases within the far-flung new communities. Even with the advanced planning called for under the existing Riverside County General Plan and for the General Plan as updated pursuant to GPA No. 960 (considered the "project" for the purposes of comparison within this alternative analysis), impacts due to traffic and circulation, as well as attendant air quality and noise impacts, are significant and unavoidable, both as direct project impacts and on a cumulative basis. This alternative is proposed as a means for addressing (lessening) this significant impact.

To combat growing sprawl, many new developments incorporate "New Urbanism" concepts that call for increased densities and intensities within community centers to create a core of concentrated homes and businesses. Though seemingly counterintuitive, increasing the density/intensity of an urban core can actually result in decreased traffic, noise and air pollution in some locations (particularly outlying areas) because compact development can create shorter commutes for shoppers, workers and others. Also, increased densities, and in particular, mixed use developments, can foster more walkable communities in which pedestrian and bicycle travel supplants vehicle trips for short distances, further reducing traffic and its attendant impacts.

As a nod to New Urbanism, the existing Riverside County General Plan was designed to include a scattering of community centers (CC LUD in the General Plan) throughout Riverside County. For this alternative, several additional community center overlays would be planned along transportation corridors/transit nodes in unincorporated portions of western Riverside County and the Coachella Valley. By placing such centers near freeways, where feasible, in addition to transit nodes, both vehicular and pedestrian travelers can be accommodated. Locations for these additional community centers include along the future Metrolink Perris Valley Extension Line and along the Amtrak commuter line extension through the Coachella Valley.

Rather than increasing the overall build out of unincorporated areas, this alternative would represent (as compared to the existing and proposed GPA No. 960) a more concentrated pattern of development intensity. To accommodate these increases, development intensity within reserve areas for the two MSHCPs would be redistributed into community centers throughout Riverside County. Thus, under this alternative the overall size of the development footprint within unincorporated Riverside County would decrease, but the overall residential density would nearly double. Gross residential density would increase from 0.42 and 0.43 for the existing and project-updated General Plans respectively, to 0.73 houses per acre under this alternative, while the overall number of units would only increase by roughly 1% (6,900) compared to the updated General Plan's total.

1. Assumptions

As defined under the existing General Plan, community centers are "purposefully designed to function differently from the typical patterns of individual, segregated land uses." Instead, "uses and activities are designed together in an integrated fashion to create a dynamic urban environment that acts as the center of activity for the surrounding area." To accomplish this, community centers are designed to accommodate "a variety of residential

densities, non-residential intensities and public spaces...integrated in a manner that promotes pedestrian activity and minimizes the dominance of the automobile."

In terms of overall land use countywide, the development (build out) scenario designed for the Added Community Center Alternative is based on the existing (2008, for the purposes of this EIR) General Plan. To it, the following specific changes were applied to accommodate the community center standards noted above:

Added Community Centers: The existing General Plan identified roughly 1,200 acres of CC and mixed-use (MUPA) land use designations throughout unincorporated Riverside County scattered across the various Area Plans with concentrations roughly focused along Interstate 15 (I-15) in southwestern Riverside County and along Interstate 10 (I-10) in the Coachella Valley region. Under this alternative, the area allotted to CCs is increased three-fold to roughly 4,800 acres. To keep community center densities high, this increase is assumed to allow for 3,600 additional acres of mixed-use, that is both high-density housing and commercial uses through overlays (i.e., alternate LUDs).

Because western Riverside County is generally more urbanized than the eastern two-thirds of Riverside County, it was assumed that roughly 1,200 acres of CC/MUPA were placed in the west. These centers would provide additional community cores along the I-15 and Interstate 215 in the Perris Valley, in particular. The new core areas in these areas would provide jobs and commercial opportunities in close proximity to housing, reducing vehicle travel to more distant locations, particularly worker commutes to Orange County. The remaining 2,400 acres of CC/MUPA are assumed to build out in eastern Riverside County, which has traditionally seen lower growth overall than to the west due to its more remote location relative to the commercial centers of Greater Los Angeles and Orange County.

In total, roughly 21,600 new high- to very high-density dwelling units (du) plus 10,500 medium-high to high-density units would be planned within the added Community Centers throughout Riverside County, accommodating an overall increase of 12,600 people and, with an equal amount of retail-commercial and associated commercial services added as well (3,600 acres total), over 90,000 additional jobs would also be added.

Open Space-Rural and Rural Density Transfer: As noted under the Agricultural Alternative, the existing General Plan includes roughly 1,930,000 acres of lands designated as open space-rural (OS-RUR). However, since much of this land has limited access, utilities or other constraints, it was assumed (for all of the alternatives) that only 65% of the total area would be potentially suitable for rural residential (OS-RUR) development (i.e., 1,254,400 acres total supporting roughly 31,400 du). The other 45% was assumed to remain vacant. As part of this alternative, of the remaining OS-RUR lands, roughly 20% (251,000 acres; 6,300 du) was assumed to remain as OS-RUR; the other 80% (1,004,400 acres; 25,100 du) were transferred to OS-C.

In a fashion similar to the Rural Density Transfer assumptions used for the Agricultural Emphasis Alternative, for this alternative the 25,100 du lost through conversion to OS-C were allowed to transfer to the added community centers. To accommodate the units lost and ensure that private property retains value, this alternative would permit the transfer of development rights from the altered acreage to the urban uses associated with the added Community Centers. The transfers would be required to remain within the Area Plan in which the OS-RUR lands are located, however, in order to prevent severely unbalancing demands on existing and future public services and infrastructure. Acreage was also reduced from the RM and RD LUDs (2,800 acres) to offset the dwelling units reallocated to the community centers. The results are increased MUPA, CC and higher-density housing as described above, totaling 6,900 more dwelling units than proposed for GPA No. 960, yet achieving 3,700 fewer homes than proposed under the original (existing) General Plan.

High Fire Hazard Reduction: In addition to accommodating urban development pressures, this alternative also addresses significant wildfire risks through the reduction of the proposed OS-RUR areas. As shown in General Plan Figure S-11 (or Figure 4.13.3 of this EIR), much of the existing OS-RUR lands are in "high" or "very high" fire hazard severity zones. By decreasing OS-RUR and increasing the areas designated OS-C (which is generally not developable), the number of additional people, structures and property allowed within these fire hazard areas would be greatly reduced. This would also greatly reduce demands for fire protective services in the outlying and remote regions of Riverside County.

Additional Assumptions: All of the general assumptions outlined at the beginning of this section also apply. There are no exceptions or changes to them for this alternative, or additional assumptions beyond those already covered above.

a. Baseline Assumptions

As with all of the other alternatives, as well as the rest of the EIR for that matter, the starting baseline assumptions for the Added Community Center Alternative are the existing physical conditions within Riverside County. Full details on these existing conditions are provided throughout the EIR and, in particular, conditions for each environmental issue are presented in the section addressing that topic. For example, Section 4.5 (Agricultural and Forestry Resources) provides information on existing Farmland designations, mapped Agricultural Preserve locations and lands designated AG LUD in the General Plan, etc., within Riverside County. These baseline conditions apply to both the incorporated and unincorporated portions of Riverside County. See Table 6.4-G for the full baseline data set used for this alternative. See the footnotes to this table for additional comments on the baseline assumptions.

b. Build Out Assumptions

For this particular alternative, it is assumed that no other changes to the General Plan are made and that the unincorporated portions of Riverside County build out as directed by the existing General Plan. The assumptions and land use changes described above were then applied, resulting in a build out scenario specific to the Added Community Center Alternative. See Table 6.4-G (Added Community Centers – Assumptions and Projections), below.

2. Environmental Implications

Pursuant to Section 15126.6(d) of the State CEQA Guidelines, Table 6.4-H (Added Community Centers Alternative – Environmental Effects Summary), below, outlines in matrix form the significant environmental effects of the Added Community Centers Alternative. A discussion of the significant environmental effects of the alternative follows, below. Where the alternative would cause a significant effect beyond that of the proposed project, it is also discussed further below.

Table 6.4-G: Added Community Centers – Assumptions and Projections

Agricultural Emphasis Alternative ASSUMPTIONS [7]	Baseline: Existing (2007) Conditions[1, 3]			Build Out: Future (2060) Conditions [2, 4, 6]

Footnotes:
1. Source for land use, existing: EIR Table 4.2-F.
2. Source for land use, build out: Modeled for alternative (Unincorporated County) and estimated from RCCDR 2012 data for "Cities, Build Out."
3. Source for socioeconomics, existing: EIR Table 4.3-G.
4. Source for socioeconomics, build out: EIR Table 4.3-G for the cities and modeled for alternative (Unincorporated County).
5. Since their incorporations occurred after the date of NOP issuance for this EIR, the cities of Eastvale and Jurupa Valley are included in the unincorporated baseline county totals, rather than the incorporated totals.
6. "Build out" conditions are those projected for full realization of the alternative's land use plans. For this alternative, the build out scenario includes the following assumptions:
   a. All development within the unincorporated portion of Riverside County occurs as directed by the existing (2008) Riverside County General Plan. No additional unincorporated lands are annexed into any cities.
   b. The incorporated portions of Riverside County fully develop (build out) according to the land uses mapped in the existing General Plans for the individual cities (as interpreted by RCCDR).
7. All values rounded to the nearest hundred. Thus, totals may not sum precisely.
8. Commercial uses include commercial-retail, commercial-office, commercial-tourist, community center and MUPA (mixed-use).
9. Industrial uses include heavy and light industry, business parks, warehouses and public facilities, as well as mining and (active) recreational uses.
10. Open space uses include conservation lands, as well as water (lakes, etc.).
11. "Other" uses encompass any not listed elsewhere and include freeways, roads, canals, etc., as well as vacant (undeveloped) lands.

Table 6.4-H: Added Community Centers Alternative - Environmental Effects Summary

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation [2]	Significant	Cumul. Significant	Relative to Proj. [4]
4.2 – Land Use							
4.2.A	Physically divide an established community.		•				=
4.2.B	Conflict with land use policies intended to avoid or mitigate an environmental effect.			•			↓
4.2.C	Conflict with any habitat conservation plan or natural community conservation plan.		•				↓
4.3 – Population and Housing							
4.3.A	Induce direct or indirect population growth.			•		•	↑↓
4.3.B	Displace residential units.			•			↓
4.3.C	Displace people.			•			↓
4.4 – Aesthetic and Visual Resources							
4.4.A	Adversely affect scenic vistas.			•		•	↓
4.4.B	Adversely affect scenic resources within State Scenic Highways.			•			↓
4.4.C	Adversely affect existing visual character.			•			↓

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul . Significant	Relative to Proj.[4]
4.4.D	Cause adverse light and glare effects.			•		•	↓
4.4.E	Interfere with nighttime use of the Palomar Astronomical Observatory.			•			↓
4.5 – Agricultural and Forestry Resources							
4.5.A	Cause the direct or indirect conversion of designated Farmlands.		•				↓
4.5.B	Encroach on or conflict with existing agricultural uses.		•				↓
4.5.C	Adversely affect forest lands and forestry uses.		•				↓
4.6 – Air Quality							
4.6.A	Conflict with air quality plans.				•	•	↓
4.6.B (1)	Cause significant construction (short-term) air emissions.				•	•	↑
4.6.B (2)	Cause significant operational (long-term) air emissions.				•	•	↓
4.6.C	Cause cumulatively significant project air quality impacts.				•	•	↓
4.6.D	Expose sensitive receptors to air pollutants.				•	•	↓
4.6.E	Expose substantial numbers of people to objectionable odors.			•			↑
4.7 – Greenhouse Gases							
4.7.A	Generate substantial greenhouse gas emissions.			•		◊	↓
4.7.B	Conflict with greenhouse gas reduction plans, policies or regulations.			•			↓
4.8 – Biological Resources							
4.8.A	Adversely affect riparian or other sensitive habitats.				•		↓
4.8.B	Cause direct and indirect impacts to protected species or their habitats.				•		↓
4.8.C	Adversely affect wetlands.				•		↓
4.8.D	Impede species movement, migration, wildlife corridors or use of wildlife nursery sites.				•		↓
4.8.E	Conflict with adopted habitat conservation plans.		•				↓
4.8.F	Conflict with local biological resource protection policies or ordinances.		•				↓
4.9 – Cultural and Paleontological Resources							
4.9.A	Adversely change the significance of historical resources.		•				↓
4.9.B	Cause the destruction of known archeological resources.			•			↓
4.9.C	Cause the destruction of unique paleontological resources or sites.		•				↓
4.9.D	Result in the disturbance of human remains.		•				↓
4.10 – Energy Resources							
4.10.A	Increase demand for electricity.		•			•	↓
4.10.B	Increase demand for natural gas.		•			•	↓
4.10.C	Cause the inefficient use of energy.		•				↓
4.11 – Flood and Dam Inundation Hazards							
4.11.A	Result in housing within flood hazard areas.		•				↓
4.11.B	Cause impediment of flows.		•				↓
4.11.C	Expose people or structures to flooding hazards, including flooding due to dam or levee failure.		•				↓
4.11.D	Cause the adverse alteration of drainage patterns or substantially increase surface runoff.		•				↓
4.11.E	Cause inundation risks due to seiche, tsunami or mudflow.		•				↓

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul . Significant	Relative to Proj.[4]
4.12 – Geology and Soils							
4.12.A	Expose people or structures to substantial adverse effects due to rupture or a known earthquake fault.			•			↑
4.12.B	Expose people or structures to substantial strong seismic groundshaking.			•		•	↑
4.12.C	Expose people or structures to substantial adverse effects due to seismic-related ground failure, including liquefaction.			•			↑
4.12.D	Expose people or structures to substantial adverse effects due to landslide.		•				↓
4.12.E	Result in substantial soil erosion or topsoil loss.			•			↓
4.12.F	Result in development on unstable geological units or soils.		•				↓
4.12.G	Result in development on expansive soil.			•			↓
4.12.H	Result in development on soils incapable of supporting septic tanks or alternative wastewater disposal systems.			•			↓
4.13 – Hazardous Materials and Safety							
4.13.A	Create a significant hazard through the routine transport, use or disposal of hazardous materials.			•			↑
4.13.B	Cause a significant hazard through the accidental release of hazardous materials.			•			↑
4.13.C	Result in hazardous emissions or related hazards within ¼-mile of a school.			•			↑
4.13.D	Result in a significant hazard due to development on a Cortese List hazardous materials site.			•			↑
4.13.E	Result in a safety hazard for people within a two-mile radius of a public or public use airport.			•			↑↓
4.13.F	Result in a safety hazard in the vicinity of a private airstrip or heliport.			•			↑↓
4.13.G	Impair or interfere with adopted emergency response or evacuation plans.		•				↓
4.13.H	Expose people or structures to significant risk due to wildland fire.		•				↓
4.14 – Mineral Resources							
4.14.A	Result in the loss of availability of delineated locally important minerals.	•					=
4.14.B	Result in the loss of availability of known mineral resources.		•				↓
4.15 – Noise							
4.15.A	Generate noise or cause noise exposure in excess of standards.			•		•	↑↓
4.15.B	Generate or cause exposure to excessive groundborne vibration.			•			↑
4.15.C	Result in a substantial permanent increase in ambient noise levels.				•	•	↑↓
4.15.D	Result in a substantial temporary or periodic increase in ambient noise.				•	•	↑
4.15.E	Expose people to excessive airport-related noise levels.		•				=
4.16 – Parks and Recreation							
4.16.A	Increase the use of existing parks or recreational facilities resulting in their substantial physical deterioration.				◊	•	↑
4.16.B	Trigger growth effects resulting in the need for additional parks or recreational facilities.			•		◊	↑
4.16.C	Result in significant adverse effects due to the need for additional parks or recreational facilities.			•			↑
4.17 – Public Facilities							
4.17.A	Cause adverse environmental effects due to the need for fire protection services.		•				↓
4.17.B	Cause adverse environmental effects due to the need for law enforcement services.			•		•	↑
4.17.C(1)	Adversely affect or exceed the permitted capacity of a landfill.			•		•	↑

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul . Significant	Relative to Proj.[4]
4.17.C(2)	Cause inconsistencies with applicable statutes and regulations related to solid waste, including the County Integrated Waste Management Plan.		•				↑
4.17.D	Cause adverse environmental effects due to the need for schools.			•		•	↑
4.17.E	Cause adverse environmental effects due to the need for library services.			•		•	↑
4.17.F	Cause adverse environmental effects due to the need for medical facilities.			•		•	↑
4.18 – Transportation and Traffic							
4.18.A	Conflict with circulation system effectiveness regulations for any transportation, including vehicular, mass transit and non-motorized travel.				•	◊	↑↓
4.18.B	Conflict with a congestion management program, including level of service (LOS) standards and travel demand measures.				•	◊	↑↓
4.18.C	Cause substantial safety risks as a result of a change in air traffic patterns.		•				↑
4.18.D	Cause substantial alterations in waterborne, rail or air traffic.		•				↑
4.18.E	Substantially increase road hazards due to design or incompatible uses.		•				↓
4.18.F	Cause an adverse effect on or need for new or altered road maintenance.		•				↓
4.18.G	Cause an adverse effect on circulation during construction.			•			↓
4.18.H	Result in inadequate emergency access.		•				↓
4.18.I	Conflict with policies for public transit or non-motorized travel, or decrease the performance or safety of such facilities.		•				↓
4.19 – Water Resources							
4.19.A	Result in insufficient water supply.				•	•	↑
4.19.B	Substantially deplete groundwater supplies or substantially interfere with groundwater recharge.				•	•	↑
4.19.C	Substantially degrade water quality.		•				↓
4.19.D	Violate water quality standards or waste discharge requirements.			•			↓
4.19.E	Exceed wastewater treatment requirements.		•				↓
4.19.F	Exceed wastewater treatment capacity.		•				↑
4.19.G	Result in significant adverse effects due to the construction of new or expanded water or wastewater facilities.			•			↑
4.19.H	Substantially alter existing drainage patterns resulting in substantial erosion or siltation.			•			↓
4.19.I	Cause runoff exceeding stormwater drainage system capacities or cause substantial water pollution.			•			↓
4.19.J	Cause significant adverse effects due to the need for new or expanded stormwater drainage facilities.			•			↓
5.2 – Significant Irreversible Changes							
5.2.A	Result in a large commitment of non-renewable resources that make later removal or non-use unlikely.				•	•	↓
5.2.B	Result in the unjustified commitment of irretrievable resources.		•				=
5.2.C	Result in primary or secondary impacts that generally commit future generations to similar uses.		•			•	↓
5.2.D	Result in an environmental accident that could cause irreversible damage.		•				↑
5.4 – Significant Growth-Inducing Effects							
5.4.A	Foster direct or indirect economic growth.				•	•	↑
5.4.B	Foster direct or indirect population growth.				•	•	↑

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
5.4.C	Result in construction of additional housing.				•	•	↑
5.4.D	Remove obstacles to population growth.		•		•	•	↓
5.4.E	Facilitate other activities leading to significant environmental effects; e.g., encroach into isolated or remote areas.		•				↓
5.4.F	Result in population increase that may strain community services or facilities.				•	•	↑

Footnotes:
1. Impacts are based on a comparison of the effects of build out of the alternative as compared to the environmental baseline. Unless noted otherwise in the text, the environmental baseline is assumed to be the same as or substantially similar to that described for the proposed project in Sections 4.0 through 5.0 of the EIR.
2. Only impacts requiring new CEQA-specific mitigation measures to reduce their impacts to less than significant are considered to be "less than significant with mitigation." (Compliance with existing laws, ordinances, regulations, etc., is assumed under CEQA.)
3. Diamond (◊) denotes an impact that is substantially greater than for the General Plan as updated per GPA No. 960.
4. Severity of projected impacts relative to proposed project (rather than environmental baseline), for comparison purposes: ↓, less severe; ↑, more severe; ↓↑ = areas of each result; and, = , approximately the same.
5. Shaded yellow boxes denote impact finding for build out of the General Plan with GPA No. 960 (per Table 5.5-AJ) for comparison.

Source: Riverside County Planning Dept., new analysis and results from EIR Sections 4.2 - 4.19 and 5.1 - 5.5, 2012.

Overall, the shifting of open space-rural land uses to high density residential and retail-commercial uses in the proposed community centers under this alternative serves a number of complimentary purposes. Even though open space conservation is increased greatly (by over 1 million acres), with the increase in urban uses, this alternative would yield an increase of nearly 7,000 dwelling units and over 90,000 jobs, plus a population increase of roughly 12,600 people as compared to build out under the General Plan as amended per the project. Compared to the existing General Plan, population and dwelling units both decrease (by 12,100 and 3,700, respectively) and jobs increase by only 56,000.

As a result of these changes, future development would be focused within existing and burgeoning community centers along existing major transportation routes. The footprint of new development within the open space and interface/wildland areas of Riverside County would be greatly reduced (by roughly 80%). The reduced footprint in these rural and open areas would better focus suburban and urban development in areas mapped and already planned for such uses, both within county unincorporated areas as well as in cities.

As shown in Table 6.4-H, this alternative would have a number of significant environmental effects (either individual, in localized areas or cumulative). Certain of these significant environmental effects would be substantially worse than those associated with the project-updated General Plan. These effects, which are discussed further below, include:

- Greenhouse gas emissions.
- Increased use of existing parks and recreational facilities.
- Growth effects resulting in the need for new or expanded parks or recreational facilities.
- Circulation system effectiveness and congestion management conflicts.
- Increased traffic levels in localized areas.

a. General Impacts

Overall, as indicated in Table 6.4-H, the Added Community Centers Alternative would generally have environmental effects similar to, but greater than, the proposed project's within the urban and suburban portions of Riverside County because of the increase in housing, jobs and population that this alternative would realize from the added community centers. Despite these increases, the elimination of the OS-RUR land use with 80% reallocated as OS-C would result in a county development footprint that is over a million acres (over 1,500 square miles) smaller than currently proposed.

Thus, in general, when compared to the environmental impacts associated with build out of the existing General Plan, this alternative would have substantially fewer significant environmental impacts related to spatial effects within the county development footprint due to the million-plus acres decrease overall. These include reductions in impacts to: land use, aesthetic and visual resources, agricultural and forestry resources, biological resources, cultural resources, flood and dam hazards, some (non-seismic) geology hazards, mineral resources, floodplains and hydrology. In particular, the decreased rural/interface area footprint would result in a substantial reduction in wildland fire risks and substantially less encroachment into isolated and remote areas.

Conversely, with its density and intensity increases within the added Community Centers in urban/suburban areas, this alternative would have increased population-driven impacts due to the roughly 12,600 additional people and 90,000-plus jobs added, including: air quality, noise, water and energy demand, exposure to seismic risks and potentially hazardous materials, increased demand for various public services and facilities, including law enforcement services, wastewater treatment, schools, libraries and medical services, as well as parks and recreational opportunities. Traffic volumes, as measured in trips per day (TPD) or vehicle miles traveled (VMT), would also increase. Where these increases would be substantially greater than those predicted for the proposed project, they are discussed in greater detail, below.

Lastly, in terms of traffic and several other environmental impacts, this alternative would have a combination of effects; that is, adverse effects would be lower in some areas and higher in other areas. As an example: the increased job opportunities created by the additional community centers would decrease the long commutes by workers into Orange County and other distant job centers, but would increase traffic locally in the areas surrounding the new job centers and commercial opportunities. See the Traffic and Circulation Impacts discussion, below, for further details. Key items related to each of these impacts are discussed more fully, below.

b. Agricultural Resource Impacts

Acreage dedicated to agricultural uses would be unchanged under this alternative. However, in general, impacts to agricultural uses, particularly conflicts between them and non-agricultural activities, would be lessen under this alternative since the overall rural development would be decreased by over a million acres. As a result of this decrease, agricultural impacts associated with this alternative, both individual (local) and cumulative, would be less than significant.

c. Housing Impacts

As noted previously, the county's RHNA indicates a perennial need for additional housing for moderate, low and very low income families. For reasons of economics and scale, higher-density housing is frequently used to provide housing types to meet these needs. Under this alternative, the reallocation of densities from OS-RUR to high density residential and mixed use includes nearly 22,200 du of multi-family residential LUDs. With their higher densities, these categories are particularly well-suited for addressing low-income housing needs. Thus, this

alternative would be a substantial improvement over the existing General Plan in terms of enabling low income housing availability. As noted previously, in addition to reducing the rural/wildland development footprint, the increased number of urban dwelling units associated with this alternative would also help the County of Riverside provide the higher-density units needed to meet fair-share RHNA targets as issued by SCAG, particularly for low-income families in western Riverside County.

d. Biological Impacts

Within Community Development Foundation areas, impacts associated with this alternative would be higher due to the increased densities and intensities. However, existing mitigation, such as compliance with the requirements of the WR-MSHCP and CV-MSHCP, would ensure that biological impacts associated with this alternative were less than significant. Compared to the project, however, this alternative would result in a substantial reduction in the extent of biological impacts due to the million-plus acre reduction in the overall size of the development footprint within Riverside County. With acreage shift, effects of human encroachment, edge effects, habitat disturbance and similar effects would be greatly reduced. As such, this alternative would have substantially fewer impacts to biological resources in the outlying areas, particularly wildlands and interface fringe areas, than either the existing General Plan or the proposed project.

e. Wildfire and Fire Protection Impacts

For similar reasons, this alternative would also provide a substantial reduction in cumulative wildfire risks and, hence, demands on fire protection services. Under the existing General Plan, over 50,000 homes would be possibly scattered throughout the million-plus acres of existing OS-RUR lands. Scattered rural residential development in remote and isolated areas is the type of development pattern most vulnerable to wildland fires. These residences are also the most problematic for fire protective services to defend, given their remote locations, unimproved (dirt) access roads and lack of readily accessible water supplies. By reallocating over half of these homes from the most rural areas of Riverside County to urban areas and reducing the overall development footprint by over a million acres, the potential for people, structures and property to be put at risk for wildland fires is greatly reduced under this alternative compared to that of either the existing General Plan or the proposed project.

f. Traffic and Circulation Impacts

As mentioned above, the changes proposed under this alternative would have several different effects on traffic and circulation. In and around the urban areas in which additional Community Centers are added, traffic would increase in relation to the increased populations living, working, shopping and visiting the new uses. Conversely, however, the reduction of dwelling units allowed in the far-flung rural and wildland portions of Riverside County would also serve to reduce traffic. Lastly, the development of a large number of new jobs in association with the commercial and related economic uses included within the added Community Centers would also reduce VMTs regionally by providing needed jobs in closer proximity to workers' homes.

All of these competing factors affecting traffic make it difficult to deduce the relative effects that would result from the proposed alternative. Thus, in this instance several land use simulations were developed and modeled via the South Coast Air Quality Management District's (SCAQMD's) CalEEMod software. The results of the modeling indicate that this alternative would result in increased air quality emissions (for example, ROG, NO_X and total PM_{10}). Based on VMTs derived by the model, the alternative would also result in roughly 50% increases in the amount of vehicle miles traveled in the county overall (specifically 62% increase over existing General Plan build out and 45% increase over project-updated General Plan build out). However, the majority of the increased

trips would be occurring in the urban centers of Riverside County; only 15% of the increase in trips would be occurring in the rural, wildland and interface portions of Riverside County. This pattern of increases reflects the urban nature of the people, homes and jobs that would be added by the additional Community Centers.

Thus, as a result of the simulation, individual and cumulative traffic impacts (i.e., items 4.18.A and 4.18.B of Table 6.4-H) were found to increase as a result of the proposed land use changes. The increased densities/intensities added for the new community centers would either exacerbate existing traffic conditions or cause existing (or future) roadways to operate at unacceptable levels of service. At the high densities/intensities proposed for the community centers, these impacts are generally significant and unavoidable for the individual intersections and roadway segments closest to these urban uses. Where resulting in new traffic impacts, they would be substantially greater than those forecast for the project-updated General Plan. To some extent, traffic impacts would be lessened by the increased use of non-motorized transportation made feasible by the compact development of the centers. However, given the nature of regional land use in Southern California, it is expected that the local traffic impacts would remain significant and unavoidable even with this mitigation.

In regards to the other circulation-related impacts, those associated with populations (e.g., exposure of people to hazards from air travel) would generally be increased slightly compared to that of the existing General Plan because of the increased population accommodated by this alternative. Conversely, in terms of spatial impacts, those related to roadways would be reduced under this alternative because of the significant decrease in the number of homes built in outlying rural and wildland fringe areas. Thus, this alternative's impacts relative to road maintenance, emergency access, public transit, etc., would all be less pronounced than that of the existing General Plan or the proposed project. The smaller development footprint in particular would make transit, walking and other alternate forms of transportation more viable within Riverside County.

g. Air Quality Impacts

In terms of air quality, the CalEEMod simulations mentioned above were also used to determine how this alternative would differ from the proposed project or existing General Plan. The results indicate that because of the increased number of homes, jobs and people associated with alternative build out, and in particular, the associated increase in VMTs, overall operational air quality emissions would be higher for this alternative. Where increases would be substantially greater than those forecast for the project, they represent new impacts to air quality associated with this alternative. Thus, under this alternative, even with the mitigation outlined in Section 4.6 of this EIR, the overall level of air pollution within Riverside County would be significant and unavoidable for reasons similar to those given for the project in Section 4.6. For example, significant short-term air quality emissions, particularly of fugitive dust (PM_{10}), would occur during construction activities, such as site preparation. Likewise, significant long-term air pollutant emissions would occur from stationary sources within Riverside County in cumulatively-significant, if not individually significant, levels that exceed applicable air quality standards.

Further, with the urban increase, the number of people living and working in the new community centers would cause more people to be exposed to short-term air pollution from adjacent construction emissions and long-term (operational) emissions from increased traffic at nearby intersections. These significant emissions would collectively result in the exposure of sensitive receptors (including children, the elderly and the infirm) to substantial air pollutants, particularly where increased densities under this alternative would increase the number of people within close proximity (500 feet or less) to freeways and other high-volume traffic sources, warehouses and other industrial uses associated with high diesel and other particulate emissions. Thus, aside from objectionable odors, this alternative would result in substantial increases in both individual (future implementing projects) and cumulative (total incremental) totals for air quality emissions. See Table 6.4-H (Impacts 4.6.A through 4.6.D).

h. Greenhouse Gas Impacts

As with air pollutants, this alternative would also generate substantially greater GHG emissions than the proposed project or the existing General Plan due to the overall increase in traffic (VMT). CalEEMod simulations estimate that annual operational CO_2e emissions would approximately mirror those of other vehicle exhaust products, yielding roughly 54% for emissions that existing General Plan build out and 61% more greenhouse gases than build out of the project-updated General Plan.

Despite these increases, however, the higher density housing and concentrated urban development plans are generally consistent with the types of changes called for by SCAG to reduce regional VMTs in Southern California and, thus, lower the State of California's overall GHGs. A key focus of CARB's AB 32 Scoping Plan is centralizing development impacts within urban areas as a means for reducing VMT. Thus, even though traffic levels may rise locally in and around the proposed additional community centers (or within Riverside County as a whole), these increases are consistent with regional plans. In particular, VMTs regionally would decrease when more workers are able to find jobs near their homes in the new community centers, rather than having to commute to distant counties, such Orange or Los Angeles for work. In addition, by reducing the overall development footprint of the unincorporated county by over a million acres and reallocating 25,000-plus homes into more urban/suburban areas, this alternative would further the VMT reduction goals established by SCAG pursuant to SB 375 and, therefore, the GHG reduction goals of AB 32 would be advanced as well.

i. Energy Impacts

The demand for energy associated with the overall net increase in homes would be offset by the improved energy efficiency associated with the smaller homes built as multiple-family housing and other higher-density products. Additional energy savings would be realized from the reduced number of homes in rural and wildland areas that would need to use electricity to pump groundwater to supply the home's potable water needs. In total, according to the CalEEMod simulations, overall energy use would decrease under this alternative; mainly due to the greater energy efficiencies afforded the high-density and intensity uses. Even with these reductions, however, increased demands for energy under this alternative would be cumulatively significant for both electricity and natural gas.

j. Noise Impacts

As with air quality and GHGs, the severity of noise impacts in a community are largely dependent upon the contributions of vehicular traffic. Thus, for this alternative, the overall VMT increase would correspond to similar cumulative increases in noise levels at build out as well. That is, on a purely traffic-volume basis, overall noise levels would be higher throughout Riverside County because of the increased homes, jobs and population.

Ambient noise would increase to, or exceed, significant levels in localized areas, particularly those of increased density/intensity within the additional Community Centers, as a result of the compact development patterns proposed. Though interior levels can generally be reduced to less-than-significant levels through various structural mitigation measures (e.g., double-paned windows, thicker wall insulation, etc.), it would not be possible to fully mitigate exterior noise levels due to the compact nature of the developments. Thus, to a large extent, these noise impacts would remain significant and unavoidable under this alternative. In particular, those locations in which existing (baseline) noise levels already exceed acceptable standards would likely be further exacerbated by the additional urban development proposed. Also, due to the widespread, incremental nature of traffic-related noise increases, it is not possible to avoid or mitigate such impacts to the hundred, or even thousands, of homes and other uses that would ultimately be exposed to excessive noise levels over time. Thus, future increases in

(long-term) ambient noise, as well as construction (short-term) noise, exceeding standards would be cumulatively significant under this alternative.

Where lands designated for rural residential (OS-RUR) would be reallocated to conserved open space (OS-C), noise impacts would be reduced because fewer homes would be built in the rural, remote and isolated portions of Riverside County. In these areas, noise levels are generally already low, but because of the natural quietness of these areas, even small additional noise sources can be bothersome. Thus, the reduced development in these areas would be very beneficial to lowering noise levels contributing to biological "edge" effects and other issues affecting the suitability of open space for wildlife use. Though less than significant in any case, overall, this alternative would have fewer rural noise impacts than build out of either the existing General Plan or the proposed project.

k. Public Facilities, Parks and Recreation Impacts

As with other population-based effects, the slight (less than 1%) increase in population that would be accommodated by this alternative (as compared to the proposed project) would result in slightly higher impacts to parks and recreational facilities and other public facilities (including schools, libraries, landfills, medical facilities, government facilities, etc.) Among other things, this would also increase the effects of use (e.g., wear and tear) on existing parks, recreational and other public facilities, as well as increase the need for additional facilities to serve the growing populace. As with the existing General Plan, this alternative would also result in a number of significant cumulative effects on public facilities as well, as shown in Table 6.4-I.

In particular, it should be noted that although the overall (countywide) increase is very small, the cumulative effects to the various public services and facilities would occur based more on locality than overall populations. Thus, the concentration of growth in key added community centers means that increased use of existing public facilities (and demand for additional facilities) would not be spread evenly across Riverside County; the increases would be focused disproportionately in the urban areas of increased density/intensity. Likewise, the decreased population and housing associated with the reduced OS-RUR land would not proportionally offset these increases.

In particular, because of the compact development proposed for the community centers and their urban settings, it is likely that such new development would doubly impose on existing recreational facilities (parks, trails, golf courses, sports fields, community pools, picnic areas, etc.). First, multi-family homes, particularly apartments and other multi-floor units, tend to have little to no individual yards or green areas. Second, in order to achieve the compact development envisioned for these community centers, the opportunities for large open areas of greenspace (such as parks and picnic grounds) would be limited. Thus, for all of these reasons, this alternative's impacts to existing parks and recreational facilities (Impact 4.16.A) was deemed significant and unavoidable, and cumulative impacts of growth effects on the need for additional parks and recreational facilities (Impact 4.16.B) were also found significant. These two types of park and recreation impacts would be substantially greater under this alternative, as compared to build out of the project-updated General Plan.

l. Water Impacts

Under this alternative, total residential water usage would be lower than both that of the project or the existing General Plan. This is because of the much lower per-household water usage associated with higher-density homes, particularly multifamily (attached) units with minimal yard or landscaping. The replacement of large, estate-sized homes, which typically are the most water-intensive type of residences, with these smaller units would achieve an appreciable savings in potable water (between 5,000-15,000 acre-feet per year [AFY] countywide).

This water savings, however, is counteracted by the increase in commercial uses also associated with the added community centers. Under this alternative, commercial and industrial water use would also increase slightly, roughly 6% over the existing General Plan or 9% over build out of the General Plan per GPA No. 960. This cumulatively net increase means that additional water supplies and the infrastructure to treat and deliver such water would be needed within unincorporated Riverside County beyond already identified existing needs.

As outlined in Section 4.19.4.D, some portions of Riverside County already cope with tightly constrained water resources. These include adjudicated groundwater basins and imported State Water Project (SWP) water, which is apportioned by the State of California and can vary greatly depending on conditions. As a result, since California's water supply is finite and the State of California has identified critical constraints related to imported water availability, build out of Riverside County pursuant to this alternative would have cumulatively significant impacts on imported water supplies. A similarly significant impact would cumulatively result for local water supplies, that is, groundwater basins. The reduction of homes permitted in rural, wildland and interface areas (OS-RUR) would partially lessen this significant impact, as fewer homes would be built in areas outside of water agency service areas were reliance on local groundwater is necessary.

Impacts to wastewater (sewage) treatment facilities are the only other impact increasing under this alternative. The greater number of homes, residents and workers accommodated by this alternative means treatment needs would be cumulatively greater than for either the existing General Plan or the project. Though increased, this impact remains less than significant because of both regulatory compliance and the greatly reduced number of homes that would be accommodated in the rural wildland and interface areas where no sanitary sewer connections are available. In much of these areas individual septic systems or other private wastewater disposal facilities would be needed to serve the scattered homes, resulting in potential water quality impacts and other adverse environmental effects.

Nevertheless, the smaller overall development footprint within Riverside County resulting from the reduction in rural and interface residential development under this alternative would also help ensure that a number of other water-related impacts of this alternative are less severe than for the project or the existing General Plan. These include: water quality degradation, potential violations of water quality standards, changes in drainage patterns, hydrology and increased erosion, and lastly, increased runoff of stormwater. In total, this alternative would have significant individual and cumulative impacts to water supplies, including groundwater (Impacts 4.19.A and 4.19.B), that, while larger, are not substantially greater than, either the existing General Plan's or the project-updated General Plan's. In all other areas for water resources, impacts would be less than significant both individually and cumulatively, mainly because of the significantly smaller development footprint associated with this alternative.

m. Significant Cumulative Impacts

In general, most of the impacts found cumulatively significant for this alternative are substantially similar to those predicted for the proposed project. However, there are a few exceptions: First and foremost, the reduced development footprint within the rural wildlands and interface areas would greatly reduce the cumulative adverse effects of certain environmental impacts in these areas. These include: effects to scenic resources within State Scenic Highways, effects to farmlands and agricultural uses, including encroachment on existing uses, disturbance of cultural, archeological or paleontological resources, potential for increased landslide risks, impairment of emergency access or evacuation, need for fire protection services and additional stormwater drainage systems, and the potential for increased runoff, erosion and siltation. It would also avoid or substantially lessen cumulatively significant wildfire risks with its greatly reduced rural development footprint and avoid significant growth-inducing effects, including cumulative, associated with activities that facilitate environmental effects and

encroachment into isolated or remote areas. Again, the million-plus acre reduction in rural footprint under this alternative would substantially lessen this impact, ensuring it is less than significant.

As shown in Table 6.4-H, a number of cumulative impacts would be significant, though substantially similar in degree as for build out pursuant to the project. Cumulative impacts that would be significant and substantially greater than for the proposed project include: air quality effects, greenhouse gas emissions, transportation effects related to traffic, and growth effects on parks and recreational facilities.

n. Growth Inducement

Although its overall development footprint is smaller, this alternative would result in a small (roughly 1%) increase in both people and homes within the urban areas of Riverside ounty and a larger increase (16%) in jobs associated with the commercial uses added in the additional community centers. As such, this alternative's growth-inducing effects would also be slightly higher than those of the proposed project. Akin to those of the project, most of this alternative's growth-inducing impacts, both individually and cumulatively, would be significant and unavoidable. This alternative would foster direct and indirect population growth and economic growth; it would also facilitate construction of additional housing. It does not, however, address existing Rural Village Study Areas (RVSAs) and Rural Village Overlays. Thus, this alternative does not remove the substantial to obstacles growth that have arisen in the existing General Plan due to lack of detailed planning for these RVSAs. This alternative would, however, have substantially less impacts than project build out in terms of facilitation of additional environmental impacts, specifically those due to encroachment into isolated or remote areas, due to the greatly reduced footprint within rural, interface and wildland areas. In total, all of the growth inducement impacts outlined in Section 5.4, except Impact 5.4.E, were found to be individually and cumulatively significant for this alternative.

o. Impacts to Cities

The proposed alternative is derived from build out of the existing Riverside County General Plan, with modifications, thus impacts to cities were not included in Table 6.4-H. Rather, it was assumed that growth within the cities would occur in accordance with each city's general plan, as required by state law. See Table 6.4-G for RCCDR estimated build out results for incorporated Riverside County.

Though not addressed separately, the significant effects of this alternative on the cities within and adjacent to unincorporated Riverside County would be limited principally to cumulative effects caused by the incremental contributions arising from development in Riverside County. These significant cumulative effects would occur in areas where additional future county development causes an impact to exceed a threshold or standard of acceptability. This would occur where development in unincorporated Riverside County areas borders cities or causes traffic, noise or other effects that carried over a municipal boundary.

In addition, the reduced rural, wildland and interface development potential may serve to drive more development into other more remote areas outside of unincorporated Riverside County (e.g., eastern San Bernardino County or northern Imperial County) as well. This would increase the cumulative effects of growth within these distant areas. In total, significant cumulative effects to cities result from this alternative would include:

- Air quality effects where emissions occurring within Riverside County would affect air pollutant levels within cities, including for short-term (construction) and long-term (operational) emissions, particularly

traffic-related emissions. Exposure of sensitive receptors within cities to air pollutants generated within Riverside County and cumulatively significant air quality impacts could also occur.

- Noise level increases within Riverside County could affect levels within cities, including for construction (short-term) and operational (long-term) emissions. In particular, traffic-related noise increases could result in cities as a result of changes in county traffic patterns and/or increased trips.

- Increased traffic within Riverside County would also result in significant traffic increases in cities where links between city and county circulation networks interface. That is, increased traffic could affect cities in two ways: First, by causing traffic slowing on county roads which would lead to slowing or backups on city roads. Second, when a county roadway becomes less able to accommodate traffic, drivers seeking alternate routes may end up traveling through cities on surface streets. Lastly, development of land uses that attract visitors (such as regional shopping malls, medical centers, universities, casinos and other large-scale uses) within unincorporated Riverside County could increase trips on city roads that lead to/link to the use within Riverside County.

- Where city parks or recreational facilities are near unincorporated areas slated for increased urban development, such facilities would likely be subject to disproportionate increased use resulting in accelerated wear-and-tear on the facilities. Depending on the availability of added recreational facilities within unincorporated Riverside County, the provision of additional facilities may not offset these city increases.

- Similar to parks, concentrated growth in specific urban areas would have disproportionate effects on individual schools and school districts within Riverside County. As a result, some school districts and facilities would see population and growth increases in excess of that experienced regionally, resulting in cumulatively considerable impacts in some cases. Similar effects would occur for public services and facilities, such as medical centers, landfills, post offices, health clinics, libraries and the like.

- In locations where cities rely upon the same groundwater basin(s) that also serve an unincorporated area, additional development within Riverside County could lead to significant demands on the city's existing water supply. Where a groundwater basin is already in overdraft, adjudicated or where future demands would exceed the recharge capability of the basin, both the city and county areas relying on the basin would be significantly affected. This may particularly be significant where additional added urban demands would be met solely by groundwater from basins shared by city water providers.

- Where cities and unincorporated areas are both served by the same water district, additional development within Riverside County could increase demand on the existing imported water supply. Since such supplies are finite and subject to factors beyond the control of the water district (e.g., rainfall amounts, State mandates, court-ordered diversions for fish species in the Sacramento/San Joaquin Delta, etc.), increases exceeding the districts' ability to meet the need would result in significant impacts.

3. Achievement of Project Objectives

In terms of the project's stated objectives, this alternative would satisfy all but one. It would provide a suitable plan for "further progress" within Riverside County, since it provides for additional urban development in Riverside County. It would provide updated technical data, simply by definition. It also would address the updated regulatory environment that future development within Riverside County would need to comply with (e.g., AB 32 and greenhouse gas reduction planning) for similar reasons, even though it would require additional

CAP measures to reduce to the additional greenhouse gas emissions associated with this alternative. Nevertheless, it could still be said to adequately meet the "address new needs" objective. It also may further the Riverside County Vision by allowing higher growth in certain urban cores, extending or enhancing "continued progress" within Riverside County. The only objective not met is that it does not include any LUD updates, and thus does not address the "updated land use" objective.

4. Conclusions

Overall, as indicated in Table 6.4-H, the Added Community Centers Alternative would enable increased growth in urban cores while lessening some the significant effects associated with the proposed project. It addresses nearly all of the significant environmental impacts identified for the project and greatly reduces a number of effects, particularly spatial impacts, as a result of the reduced development footprint.

Some, but not all, of the project's significant cumulative impacts are lessened under this alternative, however these effects are offset by the localized increases that would result within the urbanized Community Centers proposed. Specifically, due to the increase in housing, population, jobs, traffic and associated economic activity, this alternative would result in substantial individual and/or cumulative impacts in a number of areas, including greenhouse gas emissions and traffic congestion. Also, because of the disproportionate effects of growth in urban areas, this alternative would also have substantially greater impacts on existing parks and recreational facilities and cause growth effects triggering the need for additional facilities. It would also have growth-inducing effects on Riverside County, its cities and the surrounding communities, cities and counties. In all other areas, significant impacts either individually or cumulatively would be generally similar to those associated with build out of the General Plan pursuant to the project, GPA No. 960.

Taken together, this alternative addresses six of the seven areas of significant effects associated with the proposed project. However, it only substantially lessens or avoids significant impacts for one of the seven (agriculture); for air quality, noise and growth inducement, this alternative's impacts are generally similar to those of the project. Although an improvement in many ways over the project, because of the absolute limiting effect of the finite water supply availability, this alternative will cause an increase in greenhouse gas emissions and traffic congestion. For these reasons, this alternative was not deemed the environmentally superior alternative.

Further, although this alternative meets four of the five objectives of the project, it does so while increasing growth and localized urban impacts beyond that of the proposed project or existing General Plan. Thus, this alternative is not deemed the favored means for achieving the stated project objectives and, for these reasons, the Added Community Centers Alternative is not deemed the preferred alternative.

E. Green Economy Alternative

In the past decade, modern society has become increasingly focused on the need to use the planet's resources wisely and efficiently. The possibility of global climate change has further sharpened that focus, particularly in the wake of California's Global Warming Solutions Act of 2006. The state has initiated a number of plans to reduce greenhouse gas emissions, including an initiative directing California to be obtaining a third of its electricity through alternative "green" methods by 2020. As used here, "green" energy means alternatives to traditional generation methods using coal, natural gas or other non-renewable petroleum-based sources. This legislative mandate has helped fuel the impetus for the growing green energy industry in the state. With its expansive open desert noted for 360 days of sunshine a year (in Blythe), bracketed by the famously windy San Gorgonio Pass to the north and the geothermal hot springs around the Salton Sea to the south, Riverside County offers unparalleled opportunities for green alternative energy generation.

Accordingly, this alternative aims to capitalize on Riverside County's renewable energy opportunities for wind, solar and geothermal by creating "green economy" jobs and improving the jobs-housing balance within tRiverside Ccounty. To do so, it proposes changes similar to the density transfers proposed for the Added Community Center Alternative. However, in this case, half the remaining OS-RUR is instead reallocated to Public Facilities (PF) to accommodate green energy generating land uses, such as commercial wind and solar energy generation, as well as geothermal or biomass, as opportunities arise. A portion (10%) of the remainder would also be allocated to additional light industrial (LI) land uses to provide additional related and ancillary services, manufacturing and other complimentary uses. Lastly, another 50% would be shifted to open space-conservation (OS-C) to provide buffers around energy uses and also to reduce the number of residences in remote, fire-prone areas (i.e., OS-RUR designated properties in interface/wildlands).

The result of this shift would greatly increase the jobs available within Riverside County, ideally allowing more residents to work in closer proximity to their homes, rather than commute to distant cities or counties. This would improve traffic on the region's freeways and main arteries, as well as greatly reducing the air pollution and traffic noise generated in our communities. In addition to reducing energy generated from non-petroleum sources, this alternative would also aid in reducing greenhouse gas emissions by reducing commuter travel. (Vehicle trips are the number one source of greenhouse gas emissions in California.) Through these means, the Green Economy Alternative addresses a number of significant, unavoidable impacts associated with the project, in particular those resulting related to air pollution, noise, traffic and energy consumption within unincorporated Riverside County.

1. Assumptions

Accordingly, the development (build out) scenario developed for the Green Energy Alternative is based on the existing (2008 for the purposes of this EIR) General Plan. To it, the following specific changes are applied:

Green Energy Development: As per the prior alternatives, and for the same reasons, there are a total of 1,254,400 acres of OS-RUR assumed to be developable within unincorporated Riverside County. Under the Green Economy Alternative, this total is split 50-50 with half going to OS-C for conservation. Of the remaining half, most (313,600 acres) would be would be reallocated to "green energy uses" allowed under the Public Facilities ("PF") LUD; a total of 10% of the remainder (62,700 acres) would be reallocated to Light Industrial ("LI") LUD to foster growth of industries allied with green energy (solar installation companies, manufacturing facilities, etc.). This transfer of intensity to industrial and energy uses would be in place of the rural residential density type of transfers proposed for the prior two alternatives.

High Fire Hazard Reduction: In addition to addressing energy-related issues, this alternative is also designed to address wildfire hazards through the methods described under the previous two alternatives. As a result of this change, roughly 15,400 fewer homes (and nearly 60,000 fewer residents) overall would be introduced into the rural and remote portions of Riverside County. This would minimize the increase in wildfire risks to people, property and structures due to future development and also enhance the production of renewable energy, which benefits the entire region.

Additional Assumptions: All of the general assumptions outlined at the beginning of this section also apply. There are no exceptions or changes to them for this alternative, or additional assumptions beyond those already covered above.

a. Baseline Assumptions

As with all of the other alternatives, as well as the rest of the EIR for that matter, the starting baseline assumptions for the Green Economy Alternative are the existing physical conditions within Riverside County. Full details on these existing conditions are provided throughout the EIR and, in particular, conditions for each environmental issue are presented in the section addressing that topic. For example, Section 4.10 (Energy Resources) provides information on existing and projected future energy demand, including for electricity and natural gas supplies, for unincorporated Riverside County. The baseline conditions capture both the cities and unincorporated portions of Riverside County. See Table 6.4-I (Green Economy Alternative – Assumptions and Projections) for the full baseline data set used for this alternative and table footnotes for additional comments on the baseline assumptions.

b. Build Out Assumptions

For this particular alternative, the existing General Plan is assumed to build out as previously outlined, except for the changes noted in the amounts of OS-RUR, LI and PF for green energy generation and related uses within the unincorporated portions of Riverside County. The effects of these land use changes on the build out demographics of Riverside County (population, housing and job outcomes) are outlined in Table 6.4-I, below. The resultant environmental implications are summarized in Table 6.4-J (Green Economy Alternative – Environmental Effects Summary).

2. Environmental Implications

Pursuant to Section 15126.6(d) of the State CEQA Guidelines, Table 6.4-J, below, outlines in matrix form the "significant environmental effects" of the Green Economy Alternative. Discussion of the significant environmental effects noted, follow. Where the alternative would cause a significant effect beyond that of the proposed project, it is also discussed below.

Table 6.4-I: Green Economy Alternative – Assumptions and Projections

Green Economy Alternative ASSUMPTIONS [7]	Baseline: Existing (2007) Conditions [1, 3]			Build Out: Future (2060) Conditions [2, 4, 6]

Footnotes:
1. Source for land use, existing: EIR Table 4.2-F.
2. Source for land use, build out: Modeled for alternative (Unincorporated County) and estimated from RCCDR 2012 data for "Cities, Build out."
3. Source for socioeconomics, existing: EIR Table 4.3-G.

4. Source for socioeconomics, build out: EIR Table 4.3-G for the cities and modeled for alternative (Unincorporated County).
5. Since their incorporations occurred after the date of NOP issuance for this EIR, the cities of Eastvale and Jurupa Valley are included in the unincorporated baseline county totals, rather than the incorporated totals.
6. "Build out" conditions are those projected for full realization of the alternative's land use plans. For this alternative, the build out scenario includes the following assumptions:
   a. All development within the unincorporated portion of Riverside County occurs as directed by the existing (2008) Riverside County General Plan. No additional unincorporated lands are annexed into any cities.
   b. The incorporated portions of Riverside County fully develop (build out) according to the land uses mapped in the existing General Plans for the individual cities (as interpreted by RCCDR).
7. All values rounded to the nearest hundred. Thus, totals may not sum precisely.
8. Commercial uses include commercial-retail, commercial-office, commercial-tourist, community center and MUPA (mixed-use).
9. Industrial uses include heavy and light industry, business parks, warehouses and public facilities, as well as mining and (active) recreational uses.
10. Open space uses include conservation lands, as well as water (lakes, etc.).
11. "Other" uses encompass any not listed elsewhere and include freeways, roads, canals, etc., as well as vacant (undeveloped) lands.

Table 6.4-J: Green Economy Alternative – Environmental Effects Summary

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
4.2 – Land Use							
4.2.A	Physically divide an established community.		•				↓
4.2.B	Conflict with land use policies intended to avoid or mitigate an environmental effect.		•				↓
4.2.C	Conflict with any habitat conservation plan or natural community conservation plan.		•				↓
4.3 – Population and Housing							
4.3.A	Induce direct or indirect population growth.		•			•	↑
4.3.B	Displace residential units.		•				↑
4.3.C	Displace people.		•				↑
4.4 – Aesthetic and Visual Resources							
4.4.A	Adversely affect scenic vistas.				◊	•	↑
4.4.B	Adversely affect scenic resources within State Scenic Highways.				◊	•	↑
4.4.C	Adversely affect existing visual character.				◊	◊	↑
4.4.D	Cause adverse light and glare effects.		•			•	↓
4.4.E	Interfere with nighttime use of the Palomar Astronomical Observatory.		•				↓
4.5 – Agricultural and Forestry Resources							
4.5.A	Cause the direct or indirect conversion of designated Farmlands.		•				↓
4.5.B	Encroach on or conflict with existing agricultural uses.		•				↓
4.5.C	Adversely affect forest lands and forestry uses.		•				↓
4.6 – Air Quality							
4.6.A	Conflict with air quality plans.				•	•	↑
4.6.B (1)	Cause significant construction (short-term) air emissions.				•	•	↑
4.6.B (2)	Cause significant operational (long-term) air emissions.				•	•	↑
4.6.C	Cause cumulatively significant project air quality impacts.				•	•	↑
4.6.D	Expose sensitive receptors to air pollutants.				•	•	↑
4.6.E	Expose substantial numbers of people to objectionable odors.			•			↓
4.7 – Greenhouse Gases							
4.7.A	Generate substantial greenhouse gas emissions.			•		◊	↑

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
4.7.B	Conflict with greenhouse gas reduction plans, policies or regulations.			•			↑
4.8 – Biological Resources							
4.8.A	Adversely affect riparian or other sensitive habitats.			•			↓
4.8.B	Cause direct and indirect impacts to protected species or their habitats.			•			↓
4.8.C	Adversely affect wetlands.			•			↓
4.8.D	Impede species movement, migration, wildlife corridors or use of wildlife nursery sites.			•			↓
4.8.E	Conflict with adopted habitat conservation plans.		•				↓
4.8.F	Conflict with local biological resource protection policies or ordinances.		•				↓
4.9 – Cultural and Paleontological Resources							
4.9.A	Adversely change the significance of historical resources.		•				↓
4.9.B	Cause the destruction of known archeological resources.			•			↓
4.9.C	Cause the destruction of unique paleontological resources or sites.		•				↓
4.9.D	Result in the disturbance of human remains.		•				↓
4.10 – Energy Resources							
4.10.A*	Increase demand for electricity.		•				↑
4.10.B	Increase demand for natural gas.		•				↑
4.10.C	Cause the inefficient use of energy.		•				↑
4.11 – Flood and Dam Inundation Hazards							
4.11.A	Result in housing within flood hazard areas.		•				↓
4.11.B	Cause impediment of flows.		•				↓
4.11.C	Expose people or structures to flooding hazards, including flooding due to dam or levee failure.		•				↓
4.11.D	Cause the adverse alteration of drainage patterns or substantially increase surface runoff.		•				↓
4.11.E	Cause inundation risks due to seiche, tsunami or mudflow.		•				↓
4.12 – Geology and Soils							
4.12.A	Expose people or structures to substantial adverse effects due to rupture or a known earthquake fault.		•				↓
4.12.B	Expose people or structures to substantial strong seismic groundshaking.		•			•	↓
4.12.C	Expose people or structures to substantial adverse effects due to seismic-related ground failure, including liquefaction.		•				↓
4.12.D	Expose people or structures to substantial adverse effects due to landslide.		•			•	↓
4.12.E	Result in substantial soil erosion or topsoil loss.		•				↑
4.12.F	Result in development on unstable geological units or soils.		•				↓
4.12.G	Result in development on expansive soil.		•				↓
4.12.H	Result in development on soils incapable of supporting septic tanks or alternative wastewater disposal systems.		•				↓
4.13 – Hazardous Materials and Safety							
4.13.A	Create a significant hazard through the routine transport, use or disposal of hazardous materials.		•				↓
4.13.B	Cause a significant hazard through the accidental release of hazardous materials.		•				↓
4.13.C	Result in hazardous emissions or related hazards within ¼-mile of a school.		•				↓

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
4.13.D	Result in a significant hazard due to development on a Cortese List hazardous materials site.		•				↓
4.13.E	Result in a safety hazard for people within a two-mile radius of a public or public use airport.		•				↓
4.13.F	Result in a safety hazard in the vicinity of a private airstrip or heliport.		•				↓
4.13.G	Impair or interfere with adopted emergency response or evacuation plans.		•				↓
4.13.H	Expose people or structures to significant risk due to wildland fire.		•				↓
4.14 – Mineral Resources							
4.14.A	Result in the loss of availability of delineated locally-important minerals.	•					=
4.14.B	Result in the loss of availability of known mineral resources.		•				↓
4.15 – Noise							
4.15.A	Generate noise or cause noise exposure in excess of standards.				•	•	↑
4.15.B	Generate or cause exposure to excessive groundborne vibration.			•			↑
4.15.C	Result in a substantial permanent increase in ambient noise levels.				•	•	↑
4.15.D	Result in a substantial temporary or periodic increase in ambient noise.				•	•	↓
4.15.E	Expose people to excessive airport-related noise levels.		•				↓
4.16 – Parks and Recreation							
4.16.A	Increase the use of existing parks or recreational facilities resulting in their substantial physical deterioration.		•				↓
4.16.B	Trigger growth effects resulting in the need for additional parks or recreational facilities.		•				↓
4.16.C	Result in significant adverse effects due to the need for additional parks or recreational facilities.		•				↓
4.17 – Public Facilities							
4.17.A	Cause adverse environmental effects due to the need for fire protection services.		•				↓
4.17.B	Cause adverse environmental effects due to the need for law enforcement services.			•			↓
4.17.C(1)	Adversely affect or exceed the permitted capacity of a landfill.			•			↓
4.17.C(2)	Cause inconsistencies with applicable statutes and regulations related to solid waste, including the County Integrated Waste Management Plan.		•				=
4.17.D	Cause adverse environmental effects due to the need for schools.		•				↓
4.17.E	Cause adverse environmental effects due to the need for library services.			•			↓
4.17.F	Cause adverse environmental effects due to the need for medical facilities.			•			↓
4.18 – Transportation and Traffic							
4.18.A*	Conflict with circulation system effectiveness regulations for any transportation, including vehicular, mass transit and non-motorized travel.				◊	◊	↑
4.18.B*	Conflict with a congestion management program, including level of service (LOS) standards and travel demand measures.				◊	◊	↑
4.18.C	Cause substantial safety risks as a result of a change in air traffic patterns.		•				↓
4.18.D	Cause substantial alterations in waterborne, rail or air traffic.		•				↓
4.18.E	Substantially increase road hazards due to design or incompatible uses.		•				↓
4.18.F	Cause an adverse effect on or need for new or altered road maintenance.		•				↑
4.18.G	Cause an adverse effect on circulation during construction.		•				↓
4.18.H	Result in inadequate emergency access.		•				↓

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
4.18.I	Conflict with policies for public transit or non-motorized travel, or decrease the performance or safety of such facilities.		•				↓
4.19 – Water Resources							
4.19.A	Result in insufficient water supply.				•	•	↑
4.19.B	Substantially deplete groundwater supplies or substantially interfere with groundwater recharge.				•	•	↑
4.19.C	Substantially degrade water quality.		•				↓
4.19.D	Violate water quality standards or waste discharge requirements.		•				↓
4.19.E	Exceed wastewater treatment requirements.		•				↓
4.19.F	Exceed wastewater treatment capacity.		•				↓
4.19.G	Result in significant adverse effects due to the construction of new or expanded water or wastewater facilities.		•				↓
4.19.H	Substantially alter existing drainage patterns resulting in substantial erosion or siltation.		•			•	↑
4.19.I	Cause runoff exceeding stormwater drainage system capacities or cause substantial water pollution.		•				↓
4.19.J	Cause significant adverse effects due to the need for new or expanded stormwater drainage facilities.		•			•	↓
5.2 – Significant Irreversible Changes							
5.2.A	Result in a large commitment of non-renewable resources that make later removal or non-use unlikely.				•	•	↓
5.2.B	Result in the unjustified commitment of irretrievable resources.		•				↓
5.2.C	Result in primary or secondary impacts that generally commit future generations to similar uses.				•	•	↓
5.2.D	Result in an environmental accident that could cause irreversible damage.		•				↑
5.4 – Significant Growth-Inducing Effects							
5.4.A	Foster direct or indirect economic growth.				•	◊	↑
5.4.B	Foster direct or indirect population growth.				•	•	↑
5.4.C	Result in construction of additional housing.				•	•	↑
5.4.D	Remove obstacles to population growth.				•	•	↑
5.4.E	Facilitate other activities leading to significant environmental effects; e.g., encroach into isolated or remote areas.		•				↓
5.4.F	Result in population increase that may strain community services or facilities.				•	•	↓

Footnotes:
1. Impacts are based on a comparison of the effects of build out of the alternative as compared to the environmental baseline. Unless noted otherwise in the text, the environmental baseline is assumed to be the same as or substantially similar to that described for the proposed project in Sections 4.0 through 5.0 of the EIR.
2. Only impacts requiring new CEQA-specific mitigation measures to reduce their impacts to less than significant are considered to be "less than significant with mitigation." (Compliance with existing laws, etc., is assumed under CEQA.)
3. Diamond (◊) denotes an impact that is substantially greater than for the General Plan as updated per GPA No. 960.
4. Severity of projected impacts relative to proposed project (rather than environmental baseline), for comparison purposes: ↓, less severe; ↑, more severe; ↓↑ = areas of each result; and, **=** , approximately the same.
5. Yellow boxes denote finding for build out of the General Plan with GPA No. 960 (per Table 5.5-AJ) for comparison.

Source: Riverside County Planning Dept., new analysis and results from EIR Sections 4.2 - 4.19 and 5.1 - 5.5, 2012.

Overall, the shifting of open space-rural land uses to green energy, light industrial and conserved open space proposed under this alternative serves a number of complementary purposes. With the shift of housing to industrial uses, the unincorporated portion of Riverside County would offer roughly 15,400 fewer homes under

this alternative as compared to build out of the existing General Plan. This means nearly 60,000 fewer people would be accommodated as Riverside County residents, lessening the increases in demand for additional schools, parks and other public services. Despite this, the additional industrial uses could provide nearly a million additional jobs (904,500) at build out of this alternative, if fully realized. Such an increase would greatly alter Riverside County's jobs-to-housing balance and shift workers from commuting out of Riverside County for jobs to commuting into Riverside County. This influx of workers, however, would come at a cost: increased vehicular traffic and increases in other vehicle-associated impacts, such as air pollutant and greenhouse gas emissions, noise levels and wear-and-tear on roads. All of these issues are discussed more fully, below.

As shown in Table 6.4-J, this alternative would have a number of significant environmental effects (either individual, in localized areas, or cumulative). Certain of these significant environmental effects would be substantially worse than those associated with the project-updated General Plan. These effects, which are discussed further below, include:

- Greenhouse gas emissions.
- Circulation system effectiveness.
- Increased traffic levels in localized areas.
- Fostering of direct and indirect economic growth due to the large increase in available jobs proposed.

a. General Impacts

Overall, as indicated in Table 6.4-J, the Green Economy Alternative would generally have environmental effects within unincorporated Riverside County similar to, but less than the proposed project's in terms of spatial (land-based) effects because of the reduced (627,200 acres smaller) development envelope within the interface and wildland portions of Riverside County. This decrease also means fewer homes and a corresponding decrease in population (roughly 60,000 less). In terms of economic activities, however, this alternative would offer greatly higher job opportunities. However, their location in the more rural parts of Riverside County would disproportionally increase overall VMT, even if urban/suburban traffic is not severely affected. Overall, build out of the urban and suburban portions of Riverside County would be relatively similar to that of the existing General Plan, except for more workers would possibly be commuting to jobs in-county, rather than driving to more distant jobs in other counties or cities (particularly Orange County).

Thus, generally speaking, when compared to the environmental impacts associated with build out of the existing General Plan, this alternative would have substantially fewer environmental impacts related to spatial effects within the county development footprint. These include impacts to: land use, agriculture, light and glare, forestry, biological resources, cultural resources, mineral resources, floodplain and dam inundation hazards, hazardous materials risks, hydrology, geology and seismic hazards. In particular, the decreased footprint would result in a substantial reduction in wildland fire risks and substantially less encroachment into isolated and remote areas. In conjunction with this decreased development envelope, the decreased population that would be accommodated in Riverside County would also serve to lessen adverse effects in a variety of demand-driven areas, including: lower demand for electricity, natural gas and potable water for residential use, lower demand for additional parks and recreational uses, as well as fewer additional people using existing facilities and fewer additional demands across the gamut of public services and facilities, such as schools, libraries, medical services and need for fire protection and law enforcement services. It would also result in decreased hazard exposure (including seismic, geologic, hazardous substances, flooding and other risks) and exposure of fewer people to noise impacts.

b. Agricultural Resource Impacts

This alternative would not directly affect agricultural uses. Thus, it is assumed they would continue to undergo a gradual loss due to growth pressures from the urban and suburban uses in Riverside County. The development of new green energy uses adjacent to agricultural activities may, in fact, provide additional buffering between residential uses incompatible with certain agricultural uses (for example, dairies). This would help slow urban/suburban encroachment into existing agricultural areas. Overall, however, this alternative would in aggregate have slightly fewer impacts on existing and future agriculture than the proposed project because of the 627,000-acre reduction in development footprint and fewer residents accommodated in the outlying rural, wildland and interface portions of Riverside County. Thus, both direct individual impacts and the cumulative incremental impacts to agricultural and forestry resources under this alternative would be expected to be less than significant.

c. Housing Impacts

This alternative decreases the overall development footprint associated with OS-RUR residential uses and would result in 26,000 fewer homes than build out of the existing General Plan and 15,400 fewer homes than the General Plan as amended per the project. As a result, this alternative's overall adverse effects on housing and population would be slightly greater than that of either the existing General Plan or the updated General Plan. The additional housing added over time as this alternative builds out would still result in cumulatively significant impacts on population growth compared to the baseline conditions that currently exist in Riverside County. The large increase in job availability may serve to accelerate population growth and housing demand even further in Riverside County; see discussion under Growth Impacts, below.

d. Aesthetic Impacts

This alternative proposes to set aside only 627,500 acres of OS-RUR as open space. The remaining 627,200 acres would be developed as mostly green energy generating public facilities (utilities), such as geothermal stations, solar and wind farms. As a result, large swaths of Riverside County would have altered viewsheds, particularly for wind or solar generation, which require the installation of fixtures at low densities across broad areas. These uses have aesthetic viewshed effects that are distinctly different than, and not generally harmonious with, the rural estate, ranch and other more bucolic land uses traditionally associated with very low density (e.g., 20-plus-acre parcel) residential lots. For these reasons, it is likely that this alternative would have significant individual (i.e., resulting from the implementation of individual green energy projects) impacts on aesthetics and viewshed. It would also result in cumulatively considerable changes in existing visual character, with substantially greater adverse effects than those forecast for build out of the General Plan pursuant to the project.

e. Wildfire and Fire Protection Impacts

The reduced development footprint in wildlands and interface areas for this alternative would provide a substantial reduction in cumulative wildfire risks and, hence, demands on fire protection services. Under the existing General Plan, over 50,000 homes would be possible scattered throughout the million-plus acres of existing OS-RUR lands. This sort of diffuse rural residential development in remote and isolated areas introduces homes that can be extremely vulnerable to wildland fires due to their remote locations amidst wildlands with high fire fuel loads (i.e., brush, weeds, etc.). These properties present difficulties for the provision of fire protective services due to their remote locations, unimproved (dirt) access roads, lack of readily accessible water supplies and possibly steep topography (hills and canyons) which can exacerbate wildfire behavior. By reallocating 50,000-plus homes from the most rural areas of Riverside County and reducing the overall development footprint by over a

million acres (1,500-plus square miles), the potential for people, structures and property being put at risk for wildland fires is greatly reduced under this alternative compared to that of either the existing General Plan or the proposed project.

f. Traffic and Circulation Impacts

This alternative has a reduced population due to the reduced rural (OS-RUR) housing in wildlands, and vehicle trips from residents are thus reduced correspondingly. As noted above, these decreases are offset, however, by the greatly increased number of jobs that would be associated with the green industry proposed under this alternative. Increasing the number of jobs available locally can be beneficial in providing employment for Riverside County residents closer to their homes, decreasing commutes to more distant job centers, such as Orange County. Increase job opportunities can also have the opposite effect, however, and cause trips (vehicle miles traveled) to increase as a result of a net influx of commuters if green economy jobs increase Riverside County's role as a job center in its own right.

Since all of these competing factors affecting traffic make it difficult to deduce the relative effects that would result from the proposed alternative, as noted for the prior alternative, several land use simulations were developed and modeled via SCAQMD's CalEEMod software. In order to estimate air quality and greenhouse gas emissions, the model generates estimated traffic levels, since vehicles are the largest single source of air emissions in Southern California. Though greatly simplified in comparison to the data that would be derived from full traffic modeling of each alternative (which was not feasible due to time and expense, as well as the lack of specificity/detailed land use for these scenarios), these rough estimates nevertheless provide at least an indication of the overall degree to which vehicular traffic would be increasing or decreasing within Riverside County.

The results of the modeling indicate that this alternative would result in an increase of roughly 36% more miles traveled per year than that expected from build out of the existing General Plan or an increase of roughly 21% over project-updated General Plan build out. This indicates that under this alternative Riverside County would become a net importer of workers to supply the workforce needed for the proposed green energy economy (which would include jobs in energy generation, operation and light industry, as well as the construction of these uses, plus all of the supportive industries and services, such as food service, gas stations, etc.). In particular, compared to the existing General Plan's development outlook for rural areas, this alternative would result in a roughly 66% increase in VMTs, since workers would have to travel into outlying areas of Riverside County for these green economy jobs. Trips within urban areas of Riverside County would increase by a more modest 25%. For build out of the General Plan with the proposed project (GPA No. 960), however, the rural VMT increase is much lower, only 6%, because the new trips for green economy jobs would be offset by the decrease in housing allowed in the outlying OS-RUR uses. The VMT increase for urban uses however, would be roughly 29%.

As discussed under prior alternatives, when the VMTs increase, there must typically be an increase in the network's available roadway capacity in order to ensure adequate levels of service (LOS) are maintained along both the network's roadway segments and at the intersections that link these segments. In areas where existing roadway capacities are already functioning at unacceptable levels, any additional increases in traffic would contribute incrementally to cumulatively significant impacts. Further, even future roadways constructed with capacity sufficient to serve initial and projected needs could suffer similar impacts if traffic increases regionally beyond that planned for the area.

Thus, for this alternative, significant traffic impacts would consist of a combination of cumulative impacts similar to those projected for General Plan build out and GPA No. 960 for roadways already projected to operate at levels in excess of operating standards. Plus, due to the added traffic under this scenario, a number of roadway segments and intersections previously expected to operate within target ranges (LOS) (under existing General

Plan or GPA No. 960 build out) would instead fall within unacceptable LOS ranges, resulting in new significant impacts. Adverse impacts due to the need for new or altered road maintenance activities would also increase under this alternative because of the increase wear-and-tear resulting from the increased VMTs.

For other types of transportation-related impacts, their severity under this alternative depends on whether they are population driven (and hence, would decrease with the population) or VMT driven (and hence, would increase under this alternative). Accordingly, potential safety risks to people exposed to air, water or rail traffic would decrease in conjunction with the projected 60,000-person population decrease under this alternative. Impacts on accessibility and utility of pedestrian and other non-vehicular transportation modes and routes would also be improved under this alternative as a result of fewer people in outlying areas and more people living in urban regions that are more readily served by mass transit. Emergency access needs would also be less significant under this alternative due to the 50,000 fewer rural (OS-RUR) homes and people that would be allowed in wildlands and interface areas.

g. Air Quality Impacts

In terms of air quality, this alternative would have greater impacts due in large part to the projected VMT increase expected from the large increase in available jobs in Riverside County. The CalEEMod simulations run for this alternative indicate that operational air pollutant emissions (such as ROG, NO_x and PM_{10}) would increase roughly 20%-30% compared to those expected under build out of the existing General Plan or nearly 30%-40% compared to those associated with General Plan build out as altered by GPA No. 960.

These impacts would be significant but not new. EIR No. 441, certified for the existing General Plan, found there would be several significant and unavoidable air quality impacts, even after the implementation of all feasible mitigation, for both short-term (mainly construction-related) air quality emissions and for long-term (operational) emissions (from both vehicular and stationary sources). For this alternative, such impacts would similarly be significant for both the individual projects that implement the alternative and cumulatively, as indicated in Table 6.4-J.

h. Greenhouse Gas Impacts

The "California Renewables Portfolio Standard" that also arose out of AB 32, as well as other state legislation, directs electricity providers to generate (or procure) at least 33% of their energy from specific renewable sources by 2020. The green energy industry proposed under this alternative would greatly aid the State of California in achieving this standard. Ironically, however, the substantial increase in VMTs resulting from workers commuting into Riverside County to work in these industries means that GHG emissions would also increase significantly. Specifically, while operational air pollutants would increase by roughly a quarter to a third, simulations predict that under this alternative GHG emissions would more than double. In addition to vehicles, stationary source increases associated with the various energy generation and industrial uses would also contribute.

This effect seems contradictory on the surface, given the GHG reductions associated with non-fossil fuel-based energy generation. However, it must be remembered that the energy generated would be disturbed across most of Southern California (e.g., all of the territory served by Southern California Edison) or, possibly even across the Western U.S. (if the electricity is sold to other, more distant providers), and that fossil fuels would still be providing the majority of energy generation. As a result, the overall decrease in GHG emissions for Riverside County would be relatively small on a per-capita basis, particularly when compared to the direct increase in emissions added to the countywide GHG inventory as a result of the increased commuter trips from the thousands of added green-energy workers.

The result of these competing needs means that, even assuming that a Riverside County CAP was adopted and implemented as part of this alternative, this alternative would contribute cumulatively significant levels of GHGs to the region. Further, it is possible that the VMT increases would also prevent Riverside County from achieving consistency with the State of California's AB 32 regulations. Because of the competing regional factors, more advanced modeling would be needed than is feasible for the scope of this EIR. However, since a key focus of California State's Scoping Plan is reducing vehicle emissions, including through reductions in VMTs, this alternative would likely be inconsistent with this State of California goal.

As such, since this alternative includes CAP implementation, additional implementation measures, for example expansion of mass transit, light rail or other modes for reducing single-occupant vehicle trips, would have to be added to the CAP. Though specific calculations of additional GHG reductions for proposed mitigation were outside the scope of this alternatives analysis, based on the wealth of published plans and measures, both at state and regional levels, it is assumed the proposed Riverside County CAP could be amended to achieve the necessary carbon emission reductions, despite the cumulatively considerable increase in GHG emissions associated with this alternative.

i. Energy Impacts

The energy savings associated with the fewer number of homes under this alternative are offset by the large increase in industrial and energy-related land uses. Compared to the existing General Plan, this alternative would use more than twice the electricity and natural gas. Compared to Riverside County build out of the updated General Plan (with GPA No. 960), energy use under this alternative would be roughly 40% greater for both electricity and natural gas. The difference between the two is lessened by implementation of the energy conservation measures arising from the Riverside County Climate Action Plan which is included in either of these scenarios (existing General Plan build out scenario does not include the CAP). Unlike the proposed project, however, the increased availability of electricity that is presumed to arise from the green energy generated under this alternative would ensure that the project's incremental increases in electricity demand are not cumulatively considerable.

j. Noise Impacts

Because ambient noise levels, particularly in urban and suburban areas, are generated largely by vehicles, any increases in traffic volumes generally will also increase noise levels. Thus, for this alternative the projected VMT increases mean noise levels would also increase. In locations where existing (baseline) noise levels already exceed acceptable standards, the additional VMT resulting from this alternative would further exacerbate this significant impact. Due to the widespread, incremental nature of traffic-related noise increases, it is not possible to avoid or mitigate such impacts to the thousands of homes and other uses that would ultimately be exposed to excessive noise levels over time. Future increases in (long-term) ambient and short-term (construction) noise that exceed standards would be cumulatively significant under this alternative.

In areas where the development footprint is smaller (e.g., where OS-RUR homes will instead become conserved, undeveloped open space), ambient noise levels will be protected from growth increases. Overall, however, this affects relatively few people, due to the sparse levels of development at issue. Of greater significance would be noise level increases associated with the additional green energy uses developed within the rural parts of Riverside County. In addition to temporary (short-term) construction noise, industrial uses, including green energy generation, can often increase operational noise levels. Electricity generation via wind (turbines or propellers) may increase noise and vibration exposure to sensitive receptors (e.g., residents, students, patients of nursing homes,

hospitals, etc.) while they are in operation. Geothermal energy generation can be noisy if high-pressure releases from steam lines, pumps, valves or other hydraulic systems are involved.

k. Public Facilities, Parks and Recreation Impacts

As with other population-based effects, the slight (4%) decrease in population that would result under this alternative would result in slightly lower impacts to parks and recreational facilities and other public facilities (including schools, libraries, landfills, medical facilities, government facilities, etc.) Among other things, this would also slightly decrease the effects of use (e.g., wear-and-tear) on existing parks, recreational and other public facilities, as well as decrease or slightly slow the need for additional facilities to serve the growing populace. These decreases, particularly combined with the emphasis on decreasing outlying rural housing and populations, would serve to ensure that incremental impacts associated with public services, parks and recreation are not cumulatively significant under this alternative.

l. Water Impacts

Under this alternative, residential uses would decrease by roughly 15,400 units overall, leading to a decrease in the amount of potable water needed for domestic use, as well as resulting in corresponding decrease in the amount of wastewater (sewage) generated needing sanitary sewer disposal, wastewater treatment or subsurface (septic system) disposal.

Industrial uses, under this alternative, including those associated with green energy generation directly, would be substantially increased, as would their resultant water needs. Industrial and energy-related water needs would include both those associated with ordinary domestic uses, such as bathrooms, kitchens, drinking fountains, landscaping irrigation, etc., as well as industrial "process" uses specific to the industry (for example, water cooled cutting equipment, washing parts, steam production, etc.). In addition, certain energy generation systems can also have extra water needs. As an example: photovoltaic solar panels can require fairly frequent cleaning (and hence water) to maintain optimal electricity generation rates; cooling towers associated with steam-based electricity generation (whether powered by fossil fuels, biomass or other) can also use large amounts of water as the principle coolant. (In fact, the US Geological Survey estimates that on a national level "41% of all freshwater withdrawals in the United States in 2005 were for thermoelectric power operations, primarily for cooling needs" (as noted in USGS Circular No. 1344, "Estimated Use of Water in the United States in 2005," page 52, 2009).)

According to the National Renewable Energy Laboratory (NREL), since the water used is normally re-injected back into the aquifer, geothermal energy production has much fewer impacts on freshwater resources than might be expected, but the energy technology with the lowest water-use by far is wind energy, which does not use water other than for incidental human use (bathrooms, etc.) and, rarely, washing of equipment (per NREL's "A Review of Operational Water Consumption and Withdrawal Factors for Electricity Generating Technologies," table 1, 2011). Not surprisingly, water usage rates for electricity generation can vary widely depending on the exact technology used. In total, estimates indicate that this alternative's net water demand would be roughly 1.3 million to 1.4 million acre-feet per year greater at build out than for the existing General Plan or project-amended General Plan, respectively.

As result of this increased demand, additional water supplies (both potable and industrial) and the infrastructure to treat and deliver such water would be needed within unincorporated Riverside County beyond already identified existing needs. Since water availability is already outstripped by demand, the additional water demand associated with this alternative would result in significant impacts on existing water supplies; both for imported water and groundwater. Where increases would be served by existing groundwater supplies, increased demands

could result in significant drawdown or overdraft of existing groundwater basins. And, even in cases where the additional basin drawdown itself was not significant, it is likely that such increased use would contribute incrementally to a cumulatively significant impact on water basins already in overdraft or where the current basin withdrawals exceed its replenishment (which would eventually lead to depletion of the basin). Since California's water supply is finite and the State of California has identified critical constraints related to imported water availability, build out of Riverside County pursuant to this alternative would result in cumulatively significant impacts on imported water supplies.

Lastly, this alternative could also have cumulatively significant effects on existing drainage patterns. The hundreds to thousands of acres devoted to energy generation would be subject to construction-related (short-term) water quality effects from siltation and erosion of construction sites. More significantly, wide expanses of cleared land necessary for these facilities (e.g., panels for photovoltaic solar farms, mirrors for concentrated solar generation, etc.) may be at greater risk for runoff, siltation and erosion if not properly designed, installed and maintained.

m. Significant Cumulative Impacts

In general, most of the impacts found cumulatively significant for the proposed project are substantially similar to those that would occur for this alternative. However, a few exceptions exist.

First, this alternative would minimize the effects of urbanizing growth pressures on agricultural uses and limit encroachment and conflicts with existing agricultural activities, resulting in less-than-significant cumulative impacts in these areas. It would alter less vacant land overall, resulting in lessened potential for cumulatively significant impacts to spatial (ground-based) resources, such as paleontological and archeological resources, decrease residential demand for energy, decrease the people and property potentially at risk for wildfire threats in wildlands and interface fringes, and, lastly, decrease cumulative impacts on a variety of public facilities, including parks, landfills, schools, libraries and medical facilities, as well as wastewater treatment facilities and related infrastructure.

This would result in substantially greater cumulative impacts beyond those associated with the proposed project in several key areas. It would have individually and cumulatively considerable aesthetic and viewshed impacts due to the incremental effects of introducing hundreds to thousands of acres of energy-generating uses into rural areas. It would result in cumulatively significant greenhouse gas emissions and direct or indirect economic growth. It would also result in cumulatively significant impacts to existing and future roadway segments and intersections beyond those already forecast for significant impacts under either the existing General Plan or the General Plan as amended by GPA No. 960.

n. Growth Inducement

As clearly outlined above, with its slightly smaller development potential and footprint, but larger overall industrial uses, including a substantial increase in the area devoted to green energy generation, the Green Economy Alternative would accommodate a slightly smaller resident population, but a much larger workforce than the proposed project. Thus, this alternative's overall growth-inducing effects would be somewhat higher than the project's. As with those for General Plan build out pursuant to the project, most of this alternative's growth-inducing impacts would be significant and unavoidable. It would foster direct and indirect population growth. In particular, it would foster substantially greater levels of direct and indirect economic growth as a result of the nearly one million additional jobs created. It would also facilitate the construction of additional housing (presumably to supply demand created by workers looking to reduce their commutes from outlying areas).

It does not, however, address existing Rural Village Study Areas (RVSAs) and Rural Village Overlays. Thus, this alternative does not remove the substantial obstacles to growth that have arisen in the existing General Plan due to lack of detailed planning for these RVSAs. By reducing the development envelope allowed for OS-RUR in wildlands and interface areas, it does, however, prevent growth that would cause additional significant environmental effects through encroachment into these isolated and remote parts of Riverside County. It also limits to some extent the extent of population growth that would be expected, thus reducing slightly the overall potential for strain on community services and facilities, as compared to build out of either the existing General Plan or the amended plan as proposed by GPA No. 960.

o. Impacts to Cities

The proposed alternative is derived from build out of the existing Riverside County General Plan, with modifications, thus impacts to cities were not included in Table 6.4-J. Rather, it was assumed that growth within the cities would occur in accordance with each city's general plan, as required by state law. See Table 6.4-I for RCCDR estimated build out results for incorporated Riverside County.

Though not addressed separately, the significant effects of this alternative on the cities within and adjacent to unincorporated Riverside County would be limited principally to cumulative effects caused by the incremental contributions arising from development in Riverside County. These significant cumulative effects would occur in areas where additional future county development causes an impact to exceed a threshold or standard of acceptability. This would occur where development in unincorporated Riverside County areas borders cities or causes traffic, noise or other effects that carried over a municipal boundary.

The increase in jobs generated under this alternative would likely cause indirect growth in terms of both housing demand and demand for supporting retail, commercial and other services within the cities as well as unincorporated Riverside County. In addition, the reduced rural, wildland and interface development potential may serve to drive more development into other more remote areas outside of unincorporated Riverside County (e.g., eastern San Bernardino County or northern Imperial County). This would increase the cumulative effects of growth within these distant areas.

In total, significant cumulative effects to cities result from this alternative would include:

- Air quality effects where emissions occurring within Riverside County would affect air pollutant levels within cities, including for short-term (construction) and long-term (operational) emissions, particularly traffic-related emissions. Exposure of sensitive receptors within cities to air pollutants generated within Riverside County and cumulatively significant air quality impacts could also occur.

- Noise level increases within Riverside County could affect levels within cities, including for construction (short-term) and operational (long-term) emissions. In particular, traffic-related noise increases could result in cities as a result of changes in county traffic patterns and/or increased trips.

- Increased traffic within Riverside County would also result in significant traffic increases in cities where links between city and county circulation networks interface. By causing traffic slowing on county roads, slowing or backups could cascade onto city roads. Also, when a county roadway becomes less able to accommodate traffic, drivers seeking alternate routes may end up traveling through cities on surface streets. Lastly, development of land uses that attract visitors, including the job-centers proposed under this alternative, within unincorporated Riverside County could increase trips on city roads that lead to/link to the use within Riverside County.

- Although no substantial increases in urban growth are proposed under this alternative, it is possible that development in unincorporated Riverside County areas could result in increases in the number of visitors to public facilities within adjacent cities, e.g., libraries, parks, post offices, hospitals, etc. Such increases are not expected to be cumulatively considerable, however.

- In locations where cities rely upon the same groundwater basin(s) that also serve an unincorporated area, additional development within Riverside County could lead to significant demands on the city's existing water supply. Where a groundwater basin is already in overdraft, adjudicated or where future demands would exceed the recharge capability of the basin, both the city and county areas relying on the basin would be significantly affected. This may particularly be significant where additional added urban demands would be met solely by groundwater from basins shared by city water providers.

- Where cities and unincorporated areas are both served by the same water district, additional development within Riverside County could increase demand on the existing imported water supply. Since such supplies are finite and subject to factors beyond the control of the water district (e.g., rainfall amounts, state mandates, court-ordered diversions for fish species in the Sacramento/San Joaquin Delta, etc.), increases exceeding the districts' ability to meet the need would result in significant impacts.

3. Achievement of Project Objectives

In terms of the project's stated objectives, this alternative appears to satisfy all of them. It provides a suitable plan for further progress within Riverside County, particularly in terms of increasing jobs availability. Even though it does not update the RVOSAs identified in 2003 for future planning specifications, it provides an alternate plan for future development and would also provide LUD updates, thus it does addresses the updated land use objective. It would provide updated technical data, simply by definition. And, despite increased greenhouse gas emissions, it would address the updated regulatory environment that future development within Riverside County would need to comply with (e.g., AB 32 and greenhouse gas reduction planning). Thus, it is would adequately meet the address new needs objective. Lastly, it would further the Riverside County Vision, since it proposes to greatly increase jobs in the region, helping to balance a region that traditionally has more homes than jobs, while preserving open space and the quality of life for Riverside County residents. This new economy would serve to "enhance" and "extend" the "continued progress" within Riverside County.

4. Conclusions

Overall, as indicated in Table 6.4-J, the Green Economy Alternative seeks to provide the planning needed to help California, and the country, transition from the existing, petroleum-based economy to a new, cleaner "Green Economy" based on alternative energy generation and related industries. Despite the decreased reliance on fossil fuels, however, the analysis herein finds that this alternative would have environmental impacts of similar severity to those forecast for build out of the General Plan as updated per GPA No. 960. In certain areas, in fact, as summarized in Table 6.0-A, this alternative would have substantially greater significant impacts driven mostly by the large increase in jobs created in Riverside County.

While it would reduce certain *regional* impacts (such as greenhouse gases and, possibly, traffic congestion), it would do so at the expense of substantial increases in cumulative environmental impacts within Riverside County itself. In particular, key areas adversely affected are those associated with the increased number of commuters heading into Riverside County for work: increased traffic and congestion (due to increased vehicle miles traveled within the county), higher ambient noise levels (increased due to roadway traffic noise), increased localized and regional air pollution and greenhouse gas emissions. This alternative would also result in specific new significant impacts

to viewsheds and aesthetics (including scenic highways) and to roadways and intersections in which the additional traffic volumes cause LOS ranges to be exceeded above and beyond those already identified by either the existing General Plan or for this proposed project (i.e., in Section 4.18). Lastly, even though not new significant impacts, water-related impacts to domestic and groundwater supplies would also be substantially greater under this alternative.

Taken together, this alternative only addresses four of the seven areas of significant effects associated with the proposed project. Although an improvement in many ways over the project, because of the increase in jobs and the improved jobs-to-housing balance, this alternative has substantially greater adverse effects associated with this greenhouse gases, traffic and aesthetics. Even though this alternative meets all of the project objectives, it does so at the expense of greater environmental effects. For all of these reasons, this alternative would not be deemed the environmentally superior alternative.

In summary, this alternative is not an acceptable means for achieving the stated project objectives and for all of the above reasons, the Green Economy Alternative is not deemed the preferred alternative.

F. Reduced Rural Villages Alternative

The most fundamental role of a city or county's general plan is to provide a blueprint for the future growth and development expected (or desired) to occur in the jurisdiction over time. Riverside County's RCIP General Plan fundamentally accomplishes this through the dual mechanisms of the Land Use Certainty System and a corresponding set of General Plan LUDs, which are applied to all parcels under Riverside County's jurisdiction and dictate acceptable land uses in a manner roughly akin to zoning. See the Land Use and Administrative Elements of the General Plan for full details on these issues and Section 3.0 (Project Description) of this EIR for additional information relative to this project specifically.

To accommodate future development pressures in portions of unincorporated Riverside County expected to see growth, the Riverside County General Plan also includes a number of RVOs, in addition to the basic Foundation Components and LUDs. As described in the General Plan (page LU-67), RVOs allow "a concentration of development within rural areas" designed to "accommodate a range of residential and local-serving commercial, educational, cultural and recreational opportunities." As such, RVOs are designated in portions of Riverside County that, despite being currently rural (or otherwise not urbanized), are planned to grow as Riverside County's population increases over time. Thus, the "overlay" function of an RVO is that it provides a secondary General Plan LUD to allow for both the existing (typically rural) use to remain indefinitely until growth pressures make the area ripe for expanded development, at which time the alternate (typically more community development-driven) LUD included in the RVO may be utilized. In this way, future growth can be accommodated in a manner that allows for its orderly development while allowing existing rural communities to continue in their current functions.

The General Plan also includes RVO Study Areas (RVOSAs), locations in which "dispersed development patterns, physical characteristics, such as topography and floodplains, and other factors" prevented the definitive placement of an RVO prior to the October 2003 adoption of the RCIP General Plan for Riverside County. The intent for these areas is for subsequent study to result in these RVOSAs to either be finalized into specific RVOs or to be deleted entirely. This project, GPA No. 960, in fact, addresses this very issue. Part of the development process for this General Plan update included review of all existing RVOSAs in the General Plan. Planning Department staff, as advised by the General Plan Advisory Committee, finalized a number of proposals addressing RVOSAs as part of GPA No. 960. Several RVOSAs were dropped from areas no longer deemed suitable for serving future urbanizing populations (e.g., the El Cariso Village Study Area above Lake Elsinore) and several were essentially left as-is after being found not ready for additional plans (e.g., the Sky Valley RVSA in the

Western Coachella Valley, northeast of Palm Springs). See Section 3.0 for the full list and descriptions of the RVOs and RVOSAs, as well as other Policy Areas, addressed herein.

As noted throughout this EIR, both the existing General Plan and the proposed project, GPA No. 960, will accommodate and facilitate the continued growth of unincorporated Riverside County. As analyzed throughout this EIR, this ongoing growth and resultant urbanization will have a number of significant adverse environmental impacts throughout Riverside County. Thus, this alternative was conceived to address the significant effects of continued urbanization by limiting the plans designed to accommodate it in the General Plan. Accordingly, this alternative proposes to address environmental effects stemming from population growth by limiting the planned RVOs that would be incorporated into the General Plan as a result of GPA No. 960. Specifically, this alternative proposes to eliminate the two RVOs proposed under this project (Good Hope and Meadowbrook), leaving the areas with only their existing underlying rural LUDs. To counter urbanizing effects beyond the RVOSAs, this proposal also includes deleting other proposed urbanization changes from GPA No. 960, such as the Northeast Business Park Overlay and most of the Lakeland Village (i.e., Lake Elsinore Environs Policy Area) changes and also existing and proposed policies for the Anza and Aguanga areas in southern Riverside County. Full details are outlined below.

1. Assumptions

Accordingly, the development (build out) scenario developed for the Reduced Rural Villages Alternative is based on the existing (2008 for the purposes of this EIR) General Plan. To it, the following specific changes are applied:

Rural Village Removal: As described in Section 3.0, this project proposes to provide two new Rural Village Overlays over the existing General Plan's Good Hope and Meadowbrook RVOSAs. Under this alternative, these RVOs do not go forward and the existing rural LUDs are left as currently designated in the existing General Plan. Existing/proposed RVOs, RVSAs and/or Policy Areas proposed for the Aguanga and Anza areas in REMAP are also eliminated, and only the existing base LUDs would be allowed to develop.

Other Proposed Changes: Also as described in Section 3.0, this project includes a proposed overlay (Northeast Dairies Business Park Overlay) in the Lakeview/Nuevo Area Plan that would allow existing agricultural lands ("AG" LUD) presently utilized for dairies to develop in the future as a business park ("BP" LUD). This change, affecting nearly 260 acres total, would be rolled back under this alternative. Additionally, to address growth within the eastern desert portion of Riverside County, existing or proposed policy areas for Chiriaco Summit and Vista Santa Rosa (both in the Eastern Coachella Valley Area Plan) also would be eliminated. No future urbanization would be allowed under this alternative.

Effects on LUDs: In total, these changes would directly affect a variety of LUDs, including: reducing future Medium-High Density Residential (MHDR) by approximately 200 acres and Medium Density Residential (MDR) by roughly 270 acres, Commercial-Retail (CR) by 105 acres, BP by 260 acres and Light Industrial (LI) by 70 acres. In preserving the existing/ underlying rural uses, a number of LUDs would see acreages increase, including: 20 acres of Rural-Mountain (RM) residential and 710 acres of lower-density housing (Estate-Density [EDR], Very Low-Density [VLDR] and Low-Density Residential [LDR]), as well as roughly 260 acres of Agriculture. All other proposed changes affect development in ways not reflected by the General Plan LUDs applied.

Additional Assumptions: All of the general assumptions outlined at the beginning of this section also apply. There are no exceptions or changes to them for this alternative, or additional assumptions beyond those already covered above.

a. Baseline Assumptions

As with all of the other alternatives, as well as the rest of the EIR for that matter, the starting baseline assumptions for the Reduce Rural Villages Alternative are the existing physical conditions within Riverside County. Full details on these existing conditions are provided throughout the EIR and, in particular, conditions for each environmental issue are presented in the section addressing that topic. As shown in Table 6.4-K (Reduced Rural Villages Alternative – Assumptions and Projections), the baseline conditions capture both the cities and unincorporated portions of Riverside County. Also see that table's footnotes for additional comments addressing baseline assumptions.

b. Build Out Assumptions

For this particular alternative, the existing General Plan is assumed to build out as previously outlined, except for the changes noted in the amounts of RM, lower-density residential (EDR, VLDR, LDR), MDR, MHDR acreage (and corresponding numbers of dwelling units), CR, LI, BP and AG associated with the RVOs, RVOSAs and various existing and proposed policy areas throughout Riverside County. The effects of these land use changes on the build out demographics of Riverside County (population, housing and job outcomes) are outlined in Table 6.4-K, below. The resultant environmental implications are summarized in Table 6.4-L (Reduced Rural Villages Alternative – Environmental Effects Summary).

2. Environmental Implications

Pursuant to Section 15126.6(d) of the State CEQA Guidelines, Table 6.4-L, below, outlines in matrix form the "significant environmental effects" of the Reduced Rural Villages Alternative. Discussion of the significant environmental effects noted, follow. Where the alternative would cause a significant effect beyond that of the proposed project, it is also discussed below.

Overall, the reductions in development potential (residential densities and economic use intensities) proposed under this alternative serve a number of complementary purposes. The reduction in housing (11,400 fewer units than proposed for the existing General Plan) would have a corresponding effect on Riverside County population, decreasing it by 37,000 people. Similarly, the reduced commercial and industrial uses proposed would result in roughly 42,000 fewer jobs at build out. This decrease in workers would yield complementary decreases in vehicle miles traveled for commuters, reducing traffic congestion and the associated effects on air quality, greenhouse gas emissions and noise levels. The decreased population would also lessen demand for and effects on public services and facilities, such as schools, parks, etc. Unlike the prior Green Energy Alternative, this alternative's population decreases would not be offset by other proposed increases elsewhere in unincorporated Riverside County. Accordingly, this alternative does not cause any impacts that would be substantially greater than those for build out of either the existing or updated General Plans. All of these issues and more are discussed more fully, below.

Table 6.4-K: Reduced Rural Villages Alternative – Assumptions and Projections

Reduced RVOs Alternative ASSUMPTIONS[7]	Baseline: Existing (2007) Conditions[1, 3]			Build Out: Future (2060) Conditions [2, 4, 6]

Footnotes:
1. Source for land use, existing: EIR Table 4.2-F.
2. Source for land use, build out: Modeled for alternative (Unincorporated Riverside County) and estimated from RCCDR 2012 data for "Cities, Build out."
3. Source for socioeconomics, existing: EIR Table 4.3-G.
4. Source for socioeconomics, build out: EIR Table 4.3-G for the cities and modeled for alternative (Unincorporated Riverside County).
5. Since their incorporations occurred after the date of NOP issuance for this EIR, the cities of Eastvale and Jurupa Valley are included in the unincorporated baseline county totals, rather than the incorporated totals.
6. "Build out" conditions are those projected for full realization of the alternative's land use plans. For this alternative, the build out scenario includes the following assumptions:
   a. All development within the unincorporated portion of Riverside County occurs as directed by the existing (2008) Riverside County General Plan. No additional unincorporated lands are annexed into any cities.
   b. The incorporated portions of Riverside County fully develop (build out) according to the land uses mapped in the existing General Plans for the individual cities (as interpreted by RCCDR).
7. All values rounded to the nearest hundred. Thus, totals may not sum precisely.
8. Commercial uses include commercial-retail, commercial-office, commercial-tourist, community center and MUPA (mixed-use).
9. Industrial uses include heavy and light industry, business parks, warehouses and public facilities, as well as mining and (active) recreational uses.
10. Open space uses include conservation lands, as well as water (lakes, etc.).
11. "Other" uses encompass any not listed elsewhere and include freeways, roads, canals, etc., as well as vacant (undeveloped) lands.

Table 6.4-L: Reduced Rural Villages Alternative – Environmental Effects Summary

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
4.2 – Land Use							
4.2.A	Physically divide an established community.		•				=
4.2.B	Conflict with land use policies intended to avoid or mitigate an environmental effect.		•				↓
4.2.C	Conflict with any habitat conservation plan or natural community conservation plan.		•				↓
4.3 – Population and Housing							
4.3.A	Induce direct or indirect population growth.		•				↓
4.3.B	Displace residential units.		•				↓
4.3.C	Displace people.		•				↓
4.4 – Aesthetic and Visual Resources							
4.4.A	Adversely affect scenic vistas.			•		•	↑
4.4.B	Adversely affect scenic resources within State Scenic Highways.					•	↑
4.4.C	Adversely affect existing visual character.			•			↑
4.4.D	Cause adverse light and glare effects.		•			•	↑
4.4.E	Interfere with nighttime use of the Palomar Astronomical Observatory.		•				↑

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
4.5 – Agricultural and Forestry Resources							
4.5.A	Cause the direct or indirect conversion of designated Farmlands.				•	•	↑↓
4.5.B	Encroach on or conflict with existing agricultural uses.				•	•	↑↓
4.5.C	Adversely affect forest lands and forestry uses.		•				↓
4.6 – Air Quality							
4.6.A	Conflict with air quality plans.				•	•	↓
4.6.B (1)	Cause significant construction (short-term) air emissions.				•	•	↓
4.6.B (2)	Cause significant operational (long-term) air emissions.				•	•	↓
4.6.C	Cause cumulatively significant project air quality impacts.				•	•	↓
4.6.D	Expose sensitive receptors to air pollutants.				•	•	↓
4.6.E	Expose substantial numbers of people to objectionable odors.			•			↓
4.7 – Greenhouse Gases							
4.7.A	Generate substantial greenhouse gas emissions.			•			↓
4.7.B	Conflict with greenhouse gas reduction plans, policies or regulations.			•			↓
4.8 – Biological Resources							
4.8.A	Adversely affect riparian or other sensitive habitats.			•			↓
4.8.B	Cause direct and indirect impacts to protected species or their habitats.			•			↓
4.8.C	Adversely affect wetlands.			•			↓
4.8.D	Impede species movement, migration, wildlife corridors or use of wildlife nursery sites.			•			↓
4.8.E	Conflict with adopted habitat conservation plans.		•				↓
4.8.F	Conflict with local biological resource protection policies or ordinances.		•				↓
4.9 – Cultural and Paleontological Resources							
4.9.A	Adversely change the significance of historical resources.		•				↓
4.9.B	Cause the destruction of known archeological resources.			•		•	↓
4.9.C	Cause the destruction of unique paleontological resources or sites.		•			•	↓
4.9.D	Result in the disturbance of human remains.		•				↓
4.10 – Energy Resources							
4.10.A*	Increase demand for electricity.		•			•	↓
4.10.B	Increase demand for natural gas.		•			•	↓
4.10.C	Cause the inefficient use of energy.		•				↓
4.11 – Flood and Dam Inundation Hazards							
4.11.A	Result in housing within flood hazard areas.		•				↓
4.11.B	Cause impediment of flows.		•				↓
4.11.C	Expose people or structures to flooding hazards, including flooding due to dam or levee failure.		•				↓
4.11.D	Cause the adverse alteration of drainage patterns or substantially increase surface runoff.		•				↓
4.11.E	Cause inundation risks due to seiche, tsunami or mudflow.		•				↓
4.12 – Geology and Soils							
4.12.A	Expose people or structures to substantial adverse effects due to rupture or a known earthquake fault.		•				↓

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
4.12.B	Expose people or structures to substantial strong seismic groundshaking.		•			•	↓
4.12.C	Expose people or structures to substantial adverse effects due to seismic-related ground failure, including liquefaction.		•				↓
4.12.D	Expose people or structures to substantial adverse effects due to landslide.		•			•	↓
4.12.E	Result in substantial soil erosion or topsoil loss.		•				↓
4.12.F	Result in development on unstable geological units or soils.		•				↓
4.12.G	Result in development on expansive soil.		•				↓
4.12.H	Result in development on soils incapable of supporting septic tanks or alternative wastewater disposal systems.		•				↑↓
4.13 – Hazardous Materials and Safety							
4.13.A	Create a significant hazard through the routine transport, use or disposal of hazardous materials.		•				↓
4.13.B	Cause a significant hazard through the accidental release of hazardous materials.		•				↓
4.13.C	Result in hazardous emissions or related hazards within ¼-mile of a school.		•				↓
4.13.D	Result in a significant hazard due to development on a Cortese List hazardous materials site.		•				↓
4.13.E	Result in a safety hazard for people within a two-mile radius of a public or public use airport.		•				↓
4.13.F	Result in a safety hazard in the vicinity of a private airstrip or heliport.		•				↓
4.13.G	Impair or interfere with adopted emergency response or evacuation plans.		•				↓
4.13.H	Expose people or structures to significant risk due to wildland fire.		•			•	↑
4.14 – Mineral Resources							
4.14.A	Result in the loss of availability of delineated locally important minerals.	•					=
4.14.B	Result in the loss of availability of known mineral resources.		•				↓
4.15 – Noise							
4.15.A	Generate noise or cause noise exposure in excess of standards.				•	•	↓
4.15.B	Generate or cause exposure to excessive groundborne vibration.			•			↓
4.15.C	Result in a substantial permanent increase in ambient noise levels.				•	•	↓
4.15.D	Result in a substantial temporary or periodic increase in ambient noise.				•	•	↓
4.15.E	Expose people to excessive airport-related noise levels.		•				↓
4.16 – Parks and Recreation							
4.16.A	Increase the use of existing parks or recreational facilities resulting in their substantial physical deterioration.		•				↓
4.16.B	Trigger growth effects resulting in the need for additional parks or recreational facilities.		•				↓
4.16.C	Result in significant adverse effects due to the need for additional parks or recreational facilities.		•				↓
4.17 – Public Facilities							
4.17.A	Cause adverse environmental effects due to the need for fire protection services.		•			•	↑
4.17.B	Cause adverse environmental effects due to the need for law enforcement services.			•		•	↓
4.17.C(1)	Adversely affect or exceed the permitted capacity of a landfill.			•		•	↓
4.17.C(2)	Cause inconsistencies with applicable statutes and regulations related to solid waste, including the Riverside County Integrated Waste Management Plan.		•				=
4.17.D	Cause adverse environmental effects due to the need for schools.		•			•	↓

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
4.17.E	Cause adverse environmental effects due to the need for library services.			•		•	↓
4.17.F	Cause adverse environmental effects due to the need for medical facilities.			•		•	↓
4.18 – Transportation and Traffic							
4.18.A*	Conflict with circulation system effectiveness regulations for any transportation, including vehicular, mass transit and non-motorized travel.				•	•	↓
4.18.B*	Conflict with a congestion management program, including level of service (LOS) standards and travel demand measures.				•	•	↓
4.18.C	Cause substantial safety risks as a result of a change in air traffic patterns.		•				↓
4.18.D	Cause substantial alterations in waterborne, rail or air traffic.		•				↓
4.18.E	Substantially increase road hazards due to design or incompatible uses.		•				↓
4.18.F	Cause an adverse effect on or need for new or altered road maintenance.		•				↓
4.18.G	Cause an adverse effect on circulation during construction.		•				↓
4.18.H	Result in inadequate emergency access.		•				↓
4.18.I	Conflict with policies for public transit or non-motorized travel, or decrease the performance or safety of such facilities.		•				↑
4.19 – Water Resources							
4.19.A	Result in insufficient water supply.				•	•	↓
4.19.B	Substantially deplete groundwater supplies or substantially interfere with groundwater recharge.				•	•	↓
4.19.C	Substantially degrade water quality.		•				↓
4.19.D	Violate water quality standards or waste discharge requirements.		•				↑↓
4.19.E	Exceed wastewater treatment requirements.		•				↓
4.19.F	Exceed wastewater treatment capacity.		•				↓
4.19.G	Result in significant adverse effects due to the construction of new or expanded water or wastewater facilities.		•				↓
4.19.H	Substantially alter existing drainage patterns resulting in substantial erosion or siltation.		•			•	↓
4.19.I	Cause runoff exceeding stormwater drainage system capacities or cause substantial water pollution.		•			•	↓
4.19.J	Cause significant adverse effects due to the need for new or expanded stormwater drainage facilities.		•			•	↓
5.2 – Significant Irreversible Changes							
5.2.A	Result in a large commitment of non-renewable resources that make later removal or non-use unlikely.				•	•	↓
5.2.B	Result in the unjustified commitment of irretrievable resources.		•				↓
5.2.C	Result in primary or secondary impacts that generally commit future generations to similar uses.				•	•	↓
5.2.D	Result in an environmental accident that could cause irreversible damage.		•				↓
5.4 – Significant Growth-Inducing Effects							
5.4.A	Foster direct or indirect economic growth.				•	•	↓
5.4.B	Foster direct or indirect population growth.				•	•	↓
5.4.C	Result in construction of additional housing.				•	•	↓
5.4.D	Remove obstacles to population growth.				•	•	↑

Impact #	Impact Title / Description [1, 3, 5, 6]	No Impact	Less Than Signif.	Less Than Signif. With Mitigation[2]	Significant	Cumul. Significant	Relative to Proj.[4]
5.4.E	Facilitate other activities leading to significant environmental effects; e.g., encroach into isolated or remote areas.				•	•	↑
5.4.F	Result in population increase that may strain community services or facilities.				•	•	↓

Footnotes:
1. Impacts are based on a comparison of the effects of build out of the alternative as compared to the environmental baseline. Unless noted otherwise in the text, the environmental baseline is assumed to be the same as or substantially similar to that described for the proposed project in Sections 4.0 through 5.0 of the EIR.
2. Only impacts requiring new CEQA-specific mitigation measures to reduce their impacts to less than significant are considered to be "less than significant with mitigation." (Compliance with existing laws, ordinances, regulations, etc., is assumed under CEQA.)
3. Diamond (◊) denotes an impact that is substantially greater than for the General Plan as updated per GPA No. 960.
4. Severity of projected impacts relative to proposed project (rather than environmental baseline), for comparison purposes: ↓, less severe; ↑, more severe; =, approximately the same, ↓↑ = areas of each result.
5. Shaded yellow boxes denote impact finding for build out of the General Plan with GPA No. 960 (per Table 5.5-AJ) for comparison.

Source: Riverside County Planning Dept., new analysis and results from EIR Sections 4.2 - 4.19 and 5.1 - 5.5, 2012.

a. General Impacts

Overall, as indicated in Table 6.4-L, the Reduced Rural Villages Alternative would generally have environmental effects within unincorporated Riverside County similar to, but mostly less substantial than, those forecast for build out of either the existing General Plan or the General Plan as amended per the project. The fewer homes and employment-generating land uses proposed under this alternative means that increases in both population and jobs would be reduced and, with this the attendant environmental effects would be lessened as well. The reduced population at build out would mean fewer population-driven demands for increased infrastructure, public services and facilities, such as parks, schools, post offices, hospitals, etc. Fewer homes and jobs in Riverside County would also mean fewer trips within Riverside County traveled by residents and commuters, resulting in lower VMT, less wear-and-tear on roads and less congestion compared to the General Plan build out scenarios. It should be noted, however, that these effects would be slight compared to the proposed project, GPA No. 960, as this alternative's reduction in jobs and housing only average about 1% each.

In terms of spatial impacts, this alternative proposed an overall development footprint that is largely similar to that associated with the project. The exception, however, is in areas where RVOs and RVSAs are removed under this alternative (particularly in the Aguanga and Anza regions in southwestern Riverside County). These areas would have smaller development footprints with fewer attendant spatial environmental impacts. For this reason, environmental impacts associated with spatial changes (i.e., those tied directly to land itself and the resources on or in it) would generally be less significant under this alternative. This includes all of the impacts associated with: forestry resources, biological resources, including wildlife and its habitat, cultural resources, including historical and archeological artifacts and sites, paleontological resources, flooding and dam inundation hazards, hazards to or due to geology, soils or seismicity, including known earthquake faults, liquefaction zones, expansive soils, etc., exposure to hazardous materials and sites as a result of existing or past activities, and changes in hydrology, drainage or groundwater runoff. Since the areas reduced are small portions of the overall unincorporated Riverside County, the overall effect on the environment relative to these areas would be large similar to those outlined for the proposed project.

In addition, though minor in most cases, this alternative would nevertheless yield decreased impacts across most of the environmental areas examined in this EIR, particularly as compared to those associated with existing General Plan build out. As shown in Table 6.4-L, while lowered, the overall levels of significance for most of

these are roughly the same as those predicted for the proposed project. In only a few areas does this alternative differ from the project: The reduced development potential to accommodate urbanization means this alternative would be unlikely to result in cumulatively significant inducement of population growth (i.e., Impact 4.3.A). In addition, the limits on urban population increases (due to the removal of the RVOs) would also prevent cumulatively significant demands on existing parks and recreational facilities.

In a few areas, competing forces would serve to both increase impacts in some areas and decrease those in other areas; see discussion below. Lastly, this alternative was found to have overall higher impacts in two areas related. First, its encroachment effects on isolated and remote areas would likely be greater than the project's because of greater economic pressure to meet housing demands that could not be provided in more urban areas (Impact 5.4.E). This effect would also be noticeable in the cities and in the counties adjacent to Riverside County. Secondly, the reduced urbanization under this alternative would remain a greater obstacle to growth (i.e., Impact 5.4.D). Additional details, below.

b. Agricultural Resource Impacts

This alternative would not directly affect agricultural uses. Thus, it is assumed they would continue to undergo a gradual loss due to growth pressures from the urban and suburban uses in Riverside County. Also, because of the lack of developable land of higher densities within urbanizing areas, additional development could end up spreading further into rural and agricultural portions of Riverside County under this alternative. The result could be greater levels of low-density rural-residential development to meet demands which would have otherwise been served by more urban or suburban areas. Because of these competing forces, agricultural impacts in Table 6.4-L are listed as both increasing and decreasing. The net impact cannot be foreseen at this level of detail. Absent evidence otherwise, it is assumed that individual and cumulative agricultural impacts associated with this alternative would be significant in ways similar to those outlined in the analysis performed in Section 4.5 for the project.

c. Housing Impacts

On strictly a density basis, this alternative would reduce the total number of housing units accommodated within unincorporated Riverside County at build out; there would be roughly 800 fewer units compared to build out as amended by the project, or 11,400 fewer homes as compared to existing General Plan build out. Thus, population growth in Riverside County would be similarly reduced and Impact 4.3.A would not be cumulatively substantial. In addition, by not providing for Rural Villages in several potentially urbanizing areas, this alternative would also be less likely to cause displacement of people or homes due to the conversion of existing rural uses to more urban uses. In the more rural areas, the existing supply of vacant land would readily accommodate growth without substantial displacement. This alternative would also yield fewer homes on small lots, as well as condominiums, townhomes, apartments and other higher-density, more urban, products. This could cause the available inventories of small units to increase in price, disproportionately impacting those looking for affordable housing who can neither afford (nor want, possibly) a larger home or one located farther from an existing urban center. This issue is discussed further under Growth Inducing Effects.

d. Aesthetic Impacts

This alternative limits future urban development in a manner that would result in increased development pressures occurring in the rural and outlying wildlands and interface areas of tRiverside Ccounty, which might not otherwise be developed. In addition, however, this alternative reduces the potential for rural village (and other less rural) development in the Aguanga and Anza areas. As a result of the lower densities allowed in these areas,

the footprint of urbanized lands would be greatly reduced and effects to the viewshed in relation to the existing rural and undeveloped lands would be lower as well. The potential for scattered low-density rural and estate housing would remain, however. Thus, the overall impacts to aesthetics would likely be slightly higher under this alternative, though within a similar range as those projected for GPA No. 960.

e. Wildfire and Fire Protection Impacts

This alternative would place slightly decreased demands on fire protection services based solely on the overall fewer number of homes. However, by limiting future urban development, unmet development pressures would likely lead to increased homes being built in the rural and outlying wildlands and interface areas of Riverside County, which might not otherwise be developed. Homes in these areas, particularly wildland interface regions, are at the greatest risk for wildfires. Thus, the development pattern that would result under this alternative would likely result in greater overall cumulative demands for fire protective services (Impact 4.17.A) and somewhat increased hazards associated with the exposure of people and property to wildfire hazards (Impact 4.13.H).

f. Traffic and Circulation Impacts

This alternative has a reduced population due to the reduced urban housing density; vehicle trips from residents overall would thus be reduced correspondingly. The intensities of economic land uses, particularly Commercial-Retail, Business Park and Light Industrial, would also be decreased. As indicated by the CalEEMod simulation performed for this alterative, this would result in an overall decrease in the vehicle miles traveled within unincorporated Riverside County. Thus, it would be expected that wear-and-tear on roads and associated road maintenance needs would be similarly reduced.

As discussed under impacts to cities, below, however, these decreases would likely be offset by increased travel (and, hence, traffic) in other locations outside of unincorporated Riverside County, including its cities and the adjacent counties. Additionally, the increased emphasis on lower density and, in particular, rural and scattered estate-density homes under this alternative would be less likely to facilitate use of non-pedestrian transportation. This pattern would likely hinder efforts to encourage greater walking and bicycle use within Riverside County and limit use of mass transportation as well. The other areas of environmental impact associated with transportation and circulation would be substantially similar to those outlined for the project in Section 4.18.

g. Air Quality Impacts

In terms of air quality, this alternative would have fewer impacts due mainly to the projected decrease in VMT resulting from the fewer homes and jobs to be accommodated. As VMT reductions average a modest 1-4%, air quality would show similar improvements overall. This alternative's effects on criteria pollutant emissions, such as for ROG, NO_x and particulate (PM_{10}), would be greatest in urban areas where lower densities/intensities of allowed development would mean fewer pollutant sources being introduced. Further, despite its lower density and more diffuse development, the rural portions of Riverside County would contribute nearly a third of all expected emissions. Nevertheless, the emissions associated with this alternative would be both individually and cumulatively improved (though still significant) compared to either the existing General Plan or project-updated General Plan build out scenarios.

These impacts would be significant but not new. EIR No. 441, certified for the existing General Plan, found there would be several significant and unavoidable air quality impacts, even after the implementation of all feasible mitigation, for both short-term (mainly construction-related) air quality emissions and for long-term (operational) emissions (from both vehicular and stationary sources). For this alternative, such impacts would

similarly be significant for both the individual projects that implement the alternative and cumulatively, as indicated in Table 6.4-L.

h. Greenhouse Gas Impacts

For reasons similar to those for criteria pollutants, greenhouse gas emissions would also be lower under this alternative due to the reduced densities and intensities accommodated. The greater emphasis on low density housing, which tends to feature both larger lots and larger homes, would tend to increase energy use (both electricity and natural gas). However, this increase is ultimately offset by the overall decrease in homes under this alternative. With Riverside County CAP implementation, it is expected that GHG reductions would occur similar to those forecast for the updated General Plan. Most importantly, the lower VMT associated with this alternative means that mobile source (vehicular) GHG emissions also drop significantly. Overall, this alternative would be both consistent with the proposed Riverside County CAP and aid in achieving County of Riverside targets under AB 32; no GHG impacts would be significant.

i. Energy Impacts

As noted above, the energy savings associated with the fewer number of homes under this alternative are offset by the larger home types commonly built in rural and wildland areas. Nevertheless, in total, demand for electricity and natural gas would be very similar to that forecast for build out of the updated General Plan pursuant to GPA No. 960, though roughly 1-4% lower. For these reasons, this alternative is projected to have cumulatively substantial effects on both electricity and natural gas demands, as indicated in Table 6.4-L.

j. Noise Impacts

Because ambient noise levels, particularly in urban and suburban areas, are generated largely by vehicles, as traffic volumes increase, so do ambient noise levels. Thus, from existing (baseline) conditions to build out, traffic levels will increase, as will noise levels, for any of the General Plan build out scenarios or alternatives. As noted above, CalEEMod simulations indicate overall VMTs at build out for this alternative would be lower than those predicted for build out of either the existing General Plan or the project-updated General Plan. As a result, this means this alternative would have fewer noise impacts than these General Plans at build out in terms of permanent increases in ambient noise levels as well as noise exposures in excess of standards. Such reductions would be minor (1-4%) overall, however, and not uniformly spread throughout Riverside County (since noise impacts are location and distance dependent). For these reasons, overall noise impacts associated with this alternative are forecast to be substantially similar to those for the proposed project; both individually and cumulatively significant for all but two impacts, as indicated in Table 6.4-L.

k. Public Facilities, Parks and Recreation Impacts

As with other population-based effects, the slight (1-4%) decrease in population that would result under this alternative would result in slightly lower impacts to parks and recreational facilities and other public facilities (including schools, libraries, landfills, medical facilities, government facilities, etc.) Among other things, this would also slightly decrease the effects of use (e.g., wear-and-tear) on existing parks, recreational and other public facilities, as well as decrease or slightly slow the need for additional facilities to serve the growing populace. These decreases would also serve to ensure that incremental impacts associated with public services, parks and recreation are not cumulatively significant under this alternative. The sole exception to these decreases, as discussed above, is in impacts to fire protection. Because of the increased emphasis on residential development in rural, wildlands and interface areas, this alternative would have greater impacts on the need for fire protection

services. In total, as shown in Table 6.4-L, the overall pattern of significance for impacts to public facilities would be the same as that forecast for build out of the General Plan as updated pursuant to the project.

l. Water Impacts

Under this alternative, the net reduction in residential, commercial and industrial uses, though slight, would technically result in a slightly lower increase in water demand at build out as compared to the other two General Plan build out scenarios. These decreases would be seen in both the amount of potable water needed for domestic use, as well as correspondingly in the amount of wastewater (sewage) generated needing sanitary sewer disposal, wastewater treatment or subsurface (septic system) disposal.

The decreased urban densities/intensities under this alternative would also mean that impacts to water delivery and wastewater treatment infrastructure would be lower for the utilities serving these urban areas. The increased emphasis on diffuse, rural development, however, would result in more homes being built in areas outside of existing water or sewer districts. These homes would rely on privately pumped groundwater, resulting in increased impacts on the individual groundwater basins serving these areas. Similarly, new homes in much of the interface and wildland portions of unincorporated Riverside County would also rely on individual septic systems for disposal of sewage. Though of minimal effects when sited, installed and operated correctly, increasing the amount of subsurface sewage could also result in increased water quality impacts to watersheds, groundwater and related hydrology. Thus, in Table 6.4-L, impacts to water quality (Impact 4.19.C) and associated with septic systems (Impact 4.12.H) are indicated as increasing to reflect the rural situation, as well as decreasing because of the urban reductions.

In total, the decreased development allowed under this alternative means that net water and sewer demands would be lower. Yet, since decreases are only slight (1-4%), the overall pattern of water resource impacts for this alternative would be substantially the same as those resulting from build out of the project-updated General Plan. Thus, as shown in Table 6.4-L, this alternative would result in individually and cumulatively significant impacts to potable and groundwater water supplies, as well as cumulatively substantial changes in existing drainage patterns leading to erosion or siltation, runoff potentially exceeding existing stormwater drainage systems and triggering the need for new or expanded stormwater drainage facilities.

m. Significant Cumulative Impacts

In general, most of the impacts found cumulatively significant for the proposed project are substantially similar to those that would occur for this alternative. However, a few exceptions exist. First, with its reduced urban development potential, this alternative would minimize the effects of urbanizing growth pressures on population growth. It would also minimize cumulatively significant impacts to existing parks and recreational facilities. In all other areas, cumulatively impacts associated with this alternative would be substantially similar to those forecast for build out of the General Plan as updated pursuant to GPA No. 960.

n. Growth Inducement

As clearly outlined above, with its slightly smaller development potential and footprint, the Reduced Rural Villages Alternative would accommodate a slightly smaller resident population and workforce, with an attendant reduction in the growth-inducing effects. As such, this alternative's overall growth-inducing effects, both economic and population-related, would be slightly lower than the project's within unincorporated Riverside County. The reduced population growth expected would also slightly reduce the overall potential for strain on

community services and facilities, as compared to build out of either the existing General Plan or the amended plan as proposed by GPA No. 960.

In two areas, however, this alternative's impacts would be greater: First, rather than removing obstacles to population growth, by limiting the potential for urbanization in key rural areas, this alternative increased these obstacles. And, as a result, this limit would increase pressure on rural areas to develop to provide the necessary housing stock demanded in Riverside County. This pressure would also increase growth in non-county jurisdictions; see discussion under impacts to cities, below. Thus, the result of this project would be encroachment into the more isolated and remote portions of Riverside County that would have otherwise seen limited development pressure. With increased development in such areas there would be an attendant increase in the potential for other activities leading to significant environmental effects, for example, increased wildfire risks, increased pet predation, human disturbance, increases in light and sound, and other wildland-interface fringe effects. However, since the build out of the General Plan pursuant to the project would also allow increased development in interface and wildland areas (as compared to the existing General Plan), this alternative's impacts, while significant, are not considered new.

o. Impacts to Cities

The proposed alternative is derived from build out of the existing Riverside County General Plan, with modifications, thus impacts to cities were not included in Table 6.4-L. Rather, it was assumed that growth within the cities would occur in accordance with each city's general plan, as required by state law. See Table 6.4-K for RCCDR estimated build out results for incorporated Riverside County.

Though not addressed separately, the significant effects of this alternative on the cities within and adjacent to unincorporated Riverside County would be limited principally to cumulative effects caused by the incremental contributions arising from development in Riverside County. These significant cumulative effects would particularly occur in areas where additional future county development causes an impact to exceed a threshold or standard of acceptability. Examples include where development in unincorporated county areas borders cities or causes traffic, noise or other effects that carried over a municipal boundary.

Unique to this alternative, the reduced urban development potential allowed would have a ripple effect within adjacent cities and counties. Since this alternative would be less able to meet demand for smaller units, particularly affordable housing for low income families and small, multiple-family homes, such as townhomes, condominiums and apartments, development pressures for such housing stock would increase in the cities and adjacent counties. These increases would contribute to additional indirect growth for supporting retail, commercial and other services within the cities, as well as increase the cumulative effects of demand on existing and future infrastructure, including water and sewer, parks and recreational facilities, schools, hospitals, roads, etc.

In total, significant cumulative effects to cities resulting from this alternative would include:

- Air quality effects where emissions occurring within Riverside County would affect air pollutant levels within cities, including for short-term (construction) and long-term (operational) emissions, particularly traffic-related emissions. Exposure of sensitive receptors within cities to air pollutants generated within Riverside County and cumulatively significant air quality impacts could also occur.

- Noise level increases within Riverside County could affect levels within cities, including for construction (short-term) and operational (long-term) emissions. In particular, traffic-related noise increases could result in cities as a result of changes in Riverside County traffic patterns and/or increased trips from commuters added to cities.

- Increased residential development in the cities could also contribute to significant traffic increases in cities where city and county circulation networks interface. Also, when a city or county roadway becomes less able to accommodate traffic, drivers seeking alternate routes may end up traveling through cities on surface streets. Lastly, development of land uses that attract drivers, including additional housing in cities, could increase trips on city roads. All of these increases could also increase the need for road maintenance on city roads.

- By increasing pressure for urban growth in cities under this alternative, there would also be increases in the number of visitors to public facilities within adjacent cities, e.g., libraries, parks, post offices, hospitals, etc. Such increases are not expected to be cumulatively considerable, however.

- As discussed above, insufficient urban development opportunities within unincorporated Riverside County areas could lead to increased urban development, particularly of higher-density housing, within cities, inducing cumulatively significant levels of direct and indirect population growth accordingly.

- Increased urban development in cities and adjacent counties could also have effects on the viewsheds and visual character of the affected areas, leading to cumulative impacts to aesthetic and visual resources within these jurisdictions.

- Increased growth pressures in cities and adjacent counties could also result in incremental contributions to cumulative agricultural impacts in these jurisdictions due to conversion of farmlands, encroachment on existing agricultural uses and conflicts between urbanization and existing agricultural activities.

- In locations where cities rely upon the same groundwater basin(s) that also serve an unincorporated area, additional urban development pressures in cities could lead to significant demands on the city's existing water supply. Where a groundwater basin is already in overdraft, adjudicated or where future demands would exceed the recharge capability of the basin, both the city and county areas relying on the basin would be significantly affected. This may particularly be significant where additional added urban demands would be met solely by groundwater from basins shared by city water providers.

- Where cities and unincorporated areas are both served by the same water district, additional development within cities could increase demand on the existing imported water supply. Since such supplies are finite and subject to factors beyond the control of the water district (e.g., rainfall amounts, state mandates, court-ordered diversions for fish species in the Sacramento/San Joaquin Delta, etc.), increases exceeding the districts' ability to meet the need would result in significant impacts.

- Lastly, as described above, the reduced urban development potential allowed fosters direct and indirect population growth, economic growth and housing demand in adjacent cities and counties. This growth within the cities and adjacent counties could contribute incrementally to population increases that could strain community services and facilities resulting in direct or indirect impacts to services and facilities provided by these jurisdictions.

3. Achievement of Project Objectives

In terms of the project's stated objectives, this alternative does adequately meet 60% of them: It would provide LUD updates and thus addresses the updated land use objective. It would also provide updated technical data, by definition, and would address the updated regulatory environment that future development within Riverside County would need to comply with (e.g., AB 32 and greenhouse gas reduction planning) for similar reasons.

Thus, it is would meet some of the objective for meeting new needs. It would not, however, provide future planning necessary to address and accommodate the new needs related to urbanizing growth pressures on rural areas located near urban fringes. As such, it also would not accommodate further progress within Riverside County. Rather than providing plans to handle future demand for urbanizing uses within unincorporated Riverside County, this alternative actually limits further progress in terms of future development necessary to meet population growth forecast for Riverside County. Similarly, it also would not "further the County Vision," as its limits on urbanization in growing rural-fringe areas would limit, rather than enhancing or extending, continued progress within Riverside County.

4. Conclusions

Overall, as indicated in Table 6.4-L, the Reduced Rural Villages Alternative would likely cause slightly fewer significant environmental impacts within the unincorporated portions of Riverside County as a result of the small (1-4%) decrease in the number of houses, people, jobs and economic uses proposed. These slight reductions mean that impacts associated with this alternative would be largely the same or substantially similar to those forecast for build out of the General Plan as amended pursuant to the project, GPA No. 960. Particularly as a result of fewer vehicle miles traveled in Riverside County, impacts associated with traffic, noise and air quality would be lower under this alternative. A lower population at build out would also mean that risks to people, such as from seismic, flood, air travel and hazardous material use, for example, would be slightly lower. Impacts resulting from the presence of people, such as demand for parks, schools, landfills, hospitals and other public services, as well as for water, wastewater treatment, electricity, roads and other infrastructure, would also be correspondingly reduced. In most cases, however, incremental impacts in these areas would still be cumulatively substantial. Lastly, this alternative does not adequately address significant adverse effects to agriculture because the reduced potential for urbanizing development in key locations would contribute to an increase in development within areas that would otherwise remain rural and undeveloped, particularly within wildland and interface portions of Riverside County. Nor does it provide adequate plans for handling future urbanizing growth pressures and, as a result, would tend to lead to sprawling growth within the rural portions of Riverside County, particularly within the Rural Community Foundation.

In terms of environmental impacts, this alternative was found to "substantially lessen" traffic impacts because of the reduced urban areas allowed. It was also found to successfully address, though not "substantially lessen," impacts in six areas of significant effects associated with the proposed project. It was not found to cause any new significant impacts or substantially increase any already expected to be significant pursuant to project analyses. Although a slight improvement over the project, because of the reduced urban development accommodated under this alternative, it would induce significant growth within cities and adjacent counties as a result of the unmet growth pressures within the unincorporated areas.

Although a slight improvement over the project, because of the reduced urban development accommodated under this alternative, it would induce significant growth within cities and adjacent counties. Nevertheless, notwithstanding these impacts outside unincorporated Riverside County, this alternative does reduce, either slightly or substantially, a majority of the significant adverse impacts associated with the project (i.e., build out of the General Plan pursuant to GPA No. 960). For this reason, this alternative is considered the environmentally superior alternative. However, because of the limitations on future urbanization inherent in this alternative, it only meets two of five of the project objectives (40%). For this reason, despite being environmentally favorable, this alternative would not be an acceptable means for achieving the stated project objectives. Accordingly, the Reduced Rural Villages Alternative is not deemed the preferred alternative.

6.5 Environmentally Superior Alternative and Preferred Alternative

As noted at the beginning of Section 6.0, the purpose of this exercise is to determine if there are feasible alternatives that would "substantially lessen any significant effects that the project would have on the environment" (CCR Section 15021(a)(20)). Specifically, as directed under the State CEQA Guidelines, e.g., Section 15126.6(c), the alternatives analysis is intended to allow the EIR to identify the "environmentally superior alternative" and explain why alternatives other than the proposed project were rejected.

The matrix presented under Table 6.0-A at the beginning of Section 6.0 provides a summary of each alternative's major attributes relative to project objectives and their adequacy in addressing the significant environmental effects associated with the project. An analysis of each alternative selected for inclusion then follows and conclusions are made as to the relative suitability of each in terms of both meeting project objectives and reducing significant environmental effects. The environmentally superior alternative is identified. In addition, the ultimate suitability of the alternatives in terms of feasibility in meeting stated project objectives is summarized and the preferred alternative selected.

A. Environmentally Superior Alternative

Build out of the General Plan, as it would be if updated pursuant to the proposed project, GPA No. 960, would have significant, unavoidable adverse impacts on: agriculture, air quality, noise, transportation and traffic, water supplies and growth inducement. There would also be a variety of other cumulatively considerable effects.

As indicated in Table 6.0-A, only one of the alternatives (Reduced Rural Villages Alternative) was found to address nearly all of the areas of significant project impacts and not result in any new (substantially greater) environmental impacts within unincorporated Riverside County. All of the other alternatives have substantial new and/or greater impacts, though most also had areas of substantially fewer impacts as well. The end results of each alternative's analysis are summarized below.

No Build/No Growth Alternative

This alternative, one of the "no project" scenarios addressed by CEQA for comparison purposes, would entail no growth occurring at all within unincorporated Riverside County (i.e., the County of Riverside would not approve any additional development applications). The only growth occurring in Riverside County would be within its cities, which are assumed to build out according to their General Plans. Although the No Build/No Growth Alternative does include some artificial assumptions in order to "preserve the physical environment," it is nonetheless included among the alternatives considered because of its utility in providing a clear examination of the effects of future growth in the cities within Riverside County, as well as the surrounding cities and counties. Though an admittedly extreme example, it specifically serves to paint a clear picture of how these areas' growth will themselves affect the unincorporated portions of Riverside County, even in the absence of any other unincorporated growth. Under this alternative, the environmental baseline of Riverside County would be preserved in many areas, except where adversely affected by the growing demands of the cities within Riverside County (e.g., water use, traffic generation, land annexations, etc.).

As noted in Table 6.0-A, this alternative would substantially lessen many of the significant environmental impacts associated with the project-updated General Plan. However, it would also result in significant impacts in relation to transportation system effectiveness (e.g., provide inadequate Levels of Service for roadways) and water

resources (particularly due to increased demand on groundwater basins). It would also generate two new significant impacts within Riverside County in relation to inconsistencies with greenhouse gas reduction plans (particularly AB 32) and energy efficiency plans (particularly Title 24). Lastly, it would also escalate growth pressures within adjacent cities and counties; some of which could cause significant new (or worsened) impacts in these jurisdictions, for example increased strain on existing community services and facilities. See Section 6.4.A for full details.

Taken together, the substantial reduction in significant impacts associated with this alternative would make it appear to be the environmentally superior alternative addressed under CEQA. However, Section 15126.6(e)(2) of the State CEQA Guidelines notes, "If the environmentally superior alternative is the 'no project' alternative, the EIR shall also identify an environmentally superior alternative among the other alternatives."

No Project /Status Quo Alternative

As noted above, CEQA specifies analysis of a no-project alternative that would be "reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with the available infrastructure and community services." (See State CEQA Guidelines, Section 15126.6(e)). Accordingly, the No Project/Status Quo Alternative examines the environmental effects associated with abandoning the proposed project, GPA No. 960, and "doing nothing," that is, allowing unincorporated Riverside County to continue to develop as planned under the existing Riverside County General Plan. Again, as with the first alternative, analysis of this alternative provides a look at the environmental cost of maintaining the status quo. As such, this alternative serves as a lens for highlighting the environmental implications for approving (or denying) the proposed project.

As noted in Table 6.0-A, this alternative would not substantially lessen any of the significant environmental impacts associated with the project-updated General Plan, mainly because this alternative, which represents build out of the existing General Plan, would result in more people, houses, jobs, economic land uses, vehicle miles travel and related effects. Specifically, General Plan build out with implementation of project (GPA No. 960) changes would result in a reduction of roughly 2-6% fewer people, homes, jobs and economic land uses as compared to the existing General Plan. Accordingly, analysis predicts significant impacts largely in line with those forecast for the project-updated General Plan, except with a number of new significant impacts, including some substantially greater than those of the project. These new substantial impacts include: changes to existing visual character, increased greenhouse gas emissions, effects to biological resources outside of areas under an adopted MSHCP and inefficient use of energy. See Section 6.4.B for full details.

Because this alternative would have substantial environment effects in several key areas, including four new significant impacts, it is not deemed the environmentally superior alternative.

Agricultural Emphasis Alternative

Between 2000 and 2006, Riverside County loss roughly 30% of its existing agricultural lands to conversions made in the face of increasing development pressure. Although agriculture is Riverside County's largest industry in terms of dollars, agricultural decline continues as urban uses encroach upon agriculture operations and economic pressures (including the price of water supplies) make conditions ever more tenuous for Riverside County's farmers and ranchers. Not surprisingly, one of the significant impacts of build out of either the existing or updated General Plans is loss of agricultural lands to non-agricultural uses and encroachment of non-agricultural uses into agricultural areas. This alternative is proposed as a means for addressing (lessening) this significant impact by preserving existing farmlands and increasing overall agricultural uses within unincorporated Riverside

County by roughly 250,000 acres. In addition, it also addresses cumulatively significant wildfire hazards by shifting roughly 25,000 future homes in remote, wildfire-prone rural areas to more accessible urban/suburban regions.

Overall, as indicated in Table 6.4-E, the Agricultural Emphasis Alternative would cause slightly more significant environmental impacts in the growing urban and suburban portions of unincorporated Riverside County, while substantially reducing many (but not all) impacts associated with spatial effects in the rural portions of Riverside County. In several key areas, this alternative would avoid, minimize or reduce impacts found significant under the proposed project to less-than-significant levels. These include: conversion of state-designated farmlands and encroachment or conflicts with existing agricultural uses; exposure of people or structures to wildland fire risks; and, facilitation of environmental effects due to the encroachment of development into isolated or remote areas.

With its greatly reduced rural development footprint, it would also avoid cumulatively significant cumulative impacts to archeological and paleontological resources, hazards (particularly in interface and wildland areas), demand for fire protection services and effects on water resources and groundwater basins. The smaller development footprint means cumulative effects on existing hydrology and stormwater drainage systems would also be less than significant. This alternative would also avoid significant growth-inducing effects resulting from facilitating encroachment into isolated or remote areas. However, because this alternative restricts agricultural conversion, it would hinder (reduce) significant growth-inducing effects by creating (rather than removing) obstacles to population growth within Riverside County.

Lastly, this alternative would also result in several substantially greater (worse) environmental impacts, including: greatly increased demand for water, both imported and local (groundwater); increased demand for energy (electricity and natural gas) due mainly to increased agricultural uses (particularly water pumping) and related economic uses (dairies, commercial, industrial, etc.); and, increased energy use and increased off-road equipment and vehicle operations associated with agricultural uses, contributing to substantial cumulative greenhouse gas emissions. And, lastly, environmental impacts associated with the need for new or expanded water infrastructure. Except for the greenhouse gas emissions, however, none of these cumulatively significant impacts are new as compared to those of the project-updated General Plan.

Taken together, this alternative adequately addresses four of the seven areas of significant effects associated with the proposed project, including having substantial improvements over the project in terms of both agricultural impacts and on-road vehicle traffic levels. It would also, however, be associated with three areas of more severe, environmental impacts, including increased water demand and increased cumulative impacts in several areas. Although an improvement over the project in some ways, this alternative would not be the environmentally superior alternative due to the severe limitations and significant environmental impacts that would result in conjunction with the greatly increased water demand under this alternative. For these reasons, this alternative was not deemed the environmentally superior alternative.

Added Community Centers Alternative

Sprawling patterns of suburban growth in car-centric Southern California tend to result in increased traffic, noise and air pollution as vehicle travel increases within the far-flung new communities. Even with the advanced planning called for under the existing or project-updated County General Plans, impacts due to traffic and circulation, as well as attendant air quality and noise impacts, will be significant and unavoidable. This alternative is proposed as a means for addressing (lessening) this significant impact through the incorporation of an increased number of Community Centers. As defined under the existing General Plan, community centers are purposefully designed to provide land uses and activities designed in an "integrated fashion to create a dynamic urban environment that acts as the center of activity for the surrounding area." To accomplish this, community centers

are designed to accommodate "a variety of residential densities, non-residential intensities and public spaces... integrated in a manner that promotes pedestrian activity and minimizes the dominance of the automobile."

Rather than increasing the overall build out of unincorporated areas, this alternative would represent (as compared to the existing and proposed GPA No. 960) a more concentrated pattern of development intensity. To accommodate these increases, development intensity within reserve areas for the two MSHCPs would be redistributed into community centers throughout Riverside County. Thus, under this alternative the overall size of the development footprint within unincorporated Riverside County would decrease, but the overall residential density would nearly double because of increases in lands designated as community center (CC) or mixed use planning area (MUPA) through overlays.

In total, roughly 1,200 acres of additional CC/MUPA were assumed for western Riverside County along the I-15 and Interstate 215 in the Perris Valley, in particular. In addition, 2,400 acres of CC/MUPA were placed out in eastern Riverside County, which has traditionally seen lower growth overall than to the west due to its more remote location relative to the job centers of Greater Los Angeles and Orange County. In total, roughly 21,600 new high- to very high-density dwelling units plus 10,500 medium-high to high-density units would be added throughout Riverside County, accommodating an increase of 12,600 people. With an equal amount of retail-commercial and associated commercial services added as well, over 90,000 additional jobs would be created.

Overall, as indicated in Table 6.4-H, the Added Community Centers Alternative would enable increased growth in urban cores while lessening some the significant effects associated with the proposed project. It addresses nearly all of the significant environmental impacts identified for the project and greatly reduces a number of effects, particularly spatial impacts, as a result of the reduced development footprint.

Some, but not all, of the project's significant cumulative impacts would be lessened under this alternative, however these effects are offset by the localized increases that would result within the urbanized Community Centers proposed. Specifically, due to the increase in housing, population, jobs, traffic and associated economic activity, this alternative would result in substantial individual and/or cumulative impacts in a number of areas, including greenhouse gas emissions and traffic congestion. Also, because of the disproportionate effects of growth in urban areas, this alternative would also have substantially greater impacts on existing parks and recreational facilities and cause growth effects triggering the need for additional facilities. It would also have growth-inducing effects on Riverside County, its cities and the surrounding communities, cities and counties. In all other areas, significant impacts either individually or cumulatively would be generally similar to those associated with build out of the General Plan pursuant to the project, GPA No. 960.

Taken together, this alternative addresses six of the seven areas of significant effects associated with the proposed project. However, it only substantially lessens or avoids significant impacts for one of the seven (agriculture); for air quality, noise and growth inducement, this alternative's impacts are generally similar to those of the project. Although an improvement in many ways over the project, because of the absolute limiting effect of the finite water supply availability, this alternative will cause an increase in greenhouse gas emissions and traffic congestion. For these reasons, this alternative was not deemed the environmentally superior alternative.

Green Economy Alternative

In the past decade, modern society has become increasingly focused on the need to use the planet's resources wisely and efficiently. In particular, in conjunction with AB 32, California's Global Warming Solutions Act of 2006, the State of California has initiated a number of plans to reduce greenhouse gas emissions, including an initiative directing California to be obtaining a third of its electricity through alternative green methods by 2020. This legislative mandate has helped fuel the impetus for the growing green energy industry in the state. With its

expansive open desert noted for 360 days of sunshine a year (in Blythe), bracketed by the famously windy San Gorgonio Pass to the north and the geothermal hot springs around the Salton Sea to the south, Riverside County offers unparalleled opportunities for green alternative energy generation.

Accordingly, this alternative aims to capitalize on Riverside County's renewable energy opportunities for wind, solar and geothermal by creating green economy jobs and improving the jobs-housing balance within Riverside County. It would accomplish this by proposing density transfers in which half the remaining rural residential (OS-RUR) lands are reallocated to Public Facilities (PF) to accommodate green energy generating land uses, such as commercial wind and solar energy generation, as well as geothermal or biomass, as opportunities arise. A portion (10%) of the remainder would also be allocated to additional light industrial (LI) land uses to provide additional related and ancillary services, manufacturing and other complimentary uses. Lastly, another 50% would be shifted to open space-conservation (OS-C) to provide buffers around energy uses and also to reduce the number of residences in remote, fire-prone areas (i.e., OS-RUR designated properties in interface/wildlands).

The result of this shift would greatly increase the jobs available within Riverside County, ideally allowing more residents to work in closer proximity to their homes, rather than commute to distant cities or counties. This would improve traffic on the region's freeways and main arteries, as well as greatly reducing the air pollution and traffic noise generated in our communities. In addition to reducing energy generated from non-petroleum sources, this alternative would also aid in reducing greenhouse gas emissions by reducing commuter travel. (Vehicle trips are the number one source of greenhouse gas emissions in California.) Thus, the Green Economy Alternative addresses a number of significant, unavoidable impacts associated with the project, in particular those related to air pollution, noise, traffic and energy consumption in unincorporated Riverside County.

Overall, as indicated in Table 6.4-J, the Green Economy Alternative seeks to provide the planning needed to help California, and the country, transition from the existing, petroleum-based economy to a new, cleaner green economy based on alternative energy generation and related industries. Despite the decreased reliance on fossil fuels, however, the analysis herein finds that this alternative would have environmental impacts of similar severity to those forecast for build out of the General Plan as updated per GPA No. 960. In certain areas, in fact, as summarized in Table 6.0-A, this alternative would have substantially greater significant impacts driven mostly by the large increase in jobs created in Riverside County.

While it would reduce certain regional impacts (such as greenhouse gases and, possibly, traffic congestion), it would do so at the expense of substantial increases in cumulative environmental impacts within Riverside County itself. In particular, key areas adversely affected are those associated with the increased number of commuters heading into Riverside County for work: increased traffic and congestion (due to increased vehicle miles traveled within the county), higher ambient noise levels (increased due to roadway traffic noise), increased localized and regional air pollution and greenhouse gas emissions. This alternative would also result in specific new significant impacts to viewsheds and aesthetics (including scenic highways) and to roadways and intersections in which the additional traffic volumes cause LOS ranges to be exceeded above and beyond those already identified by either the existing General Plan or for this proposed project (i.e., in section 4.18). Lastly, even though not new significant impacts, water-related impacts to domestic and groundwater supplies would also be substantially greater under this alternative.

Taken together, this alternative only addresses four of the seven areas of significant effects associated with the proposed project. Although an improvement in many ways over the project, because of the increase in jobs and the improved jobs-to-housing balance, this alternative will cause substantially greater adverse effects associated with this greenhouse gases, traffic and aesthetics. Even though this alternative meets all of the project objectives, it does so at the expense of greater environmental effects. For all of these reasons, this alternative would not be deemed the environmentally superior alternative.

Reduced Rural Villages Alternative

This alternative was conceived to address the significant effects of continued urbanization by limiting the plans designed to accommodate it in the General Plan. Accordingly, this alternative proposes to address environmental effects stemming from population growth by limiting the planned RRVOs, and other overlays and policy areas, that would be incorporated into the General Plan as a result of GPA No. 960. Specifically, this alternative proposes to eliminate the two RVOs proposed under this project (Good Hope and Meadowbrook), leaving the areas with only their existing underlying rural LUDs. To counter urbanizing effects beyond the RVOSAs, this proposal also includes deleting other proposed urbanization changes from GPA No. 960, such as the Northeast Business Park Overlay, most of the Lakeland Village (i.e., Lake Elsinore Environs Policy Area) changes and also existing and proposed policies for the Anza and Aguanga areas in southern Riverside County. In addition, areas of potential future urbanization or intensification in association with the Coachella Valley, specifically Chiriaco Summit and Vista Santa Rosa, would also be eliminated under this alternative.

Overall, as indicated in Table 6.4-L, the Reduced Rural Villages Alternative would likely cause slightly fewer significant environmental impacts within the unincorporated portions of Riverside County as a result of the small (1-4%) decrease in the number of houses, people, jobs and economic uses proposed. These slight reductions mean that impacts associated with this alternative would be largely the same or substantially similar to those forecast for build out of the General Plan as amended pursuant to the project, GPA No. 960.

Particularly as a result of fewer vehicle miles traveled in Riverside County, impacts associated with traffic, noise and air quality would be lower under this alternative. A lower population at build out would also mean that risks to people, such as from seismic, flood, air travel and hazardous material use, for example, would be slightly lower. Impacts resulting from the presence of people, such as demand for parks, schools, landfills, hospitals and other public services, as well as for water, wastewater treatment, electricity, roads and other infrastructure, would also be correspondingly reduced. In most cases, however, incremental impacts in these areas would still be cumulatively substantial.

Lastly, this alternative does not adequately address significant adverse effects to agriculture because the reduced potential for urbanizing development in key locations would contribute to an increase in development within areas that would otherwise remain rural and undeveloped, particularly within wildland and interface portions of Riverside County. Nor does it provide adequate plans for handling future urbanizing growth pressures and, as a result, would tend to lead to sprawling growth within the rural portions of Riverside County, particularly within the Rural Community Foundation.

In terms of environmental impacts, this alternative was found to substantially lessen traffic impacts because of the reduced urban areas allowed. It was also found to successfully address, though not substantially lessen, impacts in six areas of significant effects associated with the proposed project. It was not found to cause any new significant impacts or substantially increase any already expected to be significant pursuant to project analyses. Although a slight improvement over the project, because of the reduced urban development accommodated under this alternative, it would induce significant growth within cities and adjacent counties as a result of the unmet growth pressures within the unincorporated areas.

Nevertheless, notwithstanding these impacts outside unincorporated Riverside County, this alternative does reduce, either slightly or substantially, a majority of the significant adverse impacts associated with the project (i.e., build out of the General Plan pursuant to GPA No. 960). For this reason, this alternative is considered the environmentally superior alternative.

B. Preferred Alternative

Although the environmentally superior alternative was identified above, the ultimate suitability of the alternatives must still be weighed against their ability to successfully achieve the stated project objectives. While CEQA notes that not all of the objectives need be attained, per CCR Section 15126.6(a)), the alternative selected must still "feasibly attain most of the basic objectives of the project" while also avoiding or substantially lessening the significant effects of the project. Accordingly, each of the alternatives was examined relative to these standards and the stated project objectives to determine whether any among them is the preferred alternative (instead of the proposed project, GPA No. 960) for achieving build out of the General Plan. These conclusions are summarized below.

No Build/No Growth Alternative

In terms of the project's stated objectives, this alternative does not satisfy several: It would not provide a suitable plan for further progress within Riverside County since it posits no growth and no development. Nor would it address new needs, since it pushes all new growth into the cities where Riverside County's General Plan does not apply. It would provide updated technical data, simply by definition, but would not provide any updated land uses within Riverside County (since no further development would be permitted). And, most particularly, it does not further the Riverside County Vision in any way since it does not permit or promote any continued progress within Riverside County. Thus, in total, this alternative meets only one of five of the objectives of the project and it, therefore, is not considered an acceptable means for achieving the stated project objectives. For all of these reasons, despite being found environmentally superior to the proposed project, the No Build/No Growth Alternative is not deemed the preferred alternative.

No Project /Status Quo Alternative

In terms of the project's stated objectives, this alternative does not satisfy several: It would not provide a suitable plan for further progress within Riverside County since it does not update the study areas identified in 2003 for future planning specifications. It does not include any LUD updates and thus does not address the updated land use objective. It does not address the updated regulatory environment that future development within Riverside County would need to comply with (e.g., AB 32 and greenhouse gas reduction planning). Thus, this alternative does not satisfy the address new needs objective. It would provide updated technical data, simply by definition. Lastly, it does not further the Riverside County Vision in any way since it does not enhance or extend the continued progress within Riverside County. Since this alternative meets only one of five of the objectives of the project, it is not considered an acceptable means for achieving the stated project objectives. For all of these reasons, the No Project/Status Quo Alternative is not deemed the preferred alternative.

Agricultural Emphasis Alternative

In terms of the project's stated objectives, this alternative does not satisfy several: It would not provide a suitable plan for further progress within Riverside County since it does not update the study areas identified in 2003 for future planning specifications. It does not include any LUD updates and thus does not address the updated land use objective. It would provide updated technical data, simply by definition. It also would address the updated regulatory environment that future development within Riverside County and would need to comply with (e.g., AB 32 and greenhouse gas reduction planning) for similar reasons. It would not, however, fully comply with AB 32 due to the substantial increase in greenhouse gas emissions associated with this alternative. Nevertheless, this alternative could be said to adequately meet the "address new needs" objective. It does not, however, further the

Riverside County Vision in regards to growth since the restrictions on agricultural conversion would significantly hinder (not enhance or extend) continued progress within Riverside County. Overall, this alternative only meets two of five of the objectives of the project, thus it is not an acceptable means for achieving the stated project objectives. For all of these reasons, the Agricultural Emphasis Alternative is not deemed the preferred alternative.

Added Community Centers Alternative

In terms of the project's stated objectives, this alternative would satisfy all but one. It would provide a suitable plan for further progress within Riverside County, since it provides for additional urban development in Riverside County. It would provide updated technical data, simply by definition. It also would address the updated regulatory environment that future development within Riverside County would need to comply with (e.g., AB 32 and greenhouse gas reduction planning) for similar reasons, even though it would require additional CAP measures to reduce to the additional greenhouse gas emissions associated with this alternative. Nevertheless, it could still be said to adequately meet the "address new needs" objective. It also may further the Riverside County Vision by allowing higher growth in certain urban cores, extending or enhancing "continued progress" within Riverside County. The only objective not met is that it does not include any LUD updates, and thus does not address the updated land use objective. In total, although this alternative meets four of the five objectives of the project, it does so while increasing growth and localized urban impacts beyond that of the proposed project or existing General Plan. Thus, this alternative is not deemed the favored means for achieving the stated project objectives. For all of these reasons, the Added Community Centers Alternative is not deemed the preferred alternative.

Green Economy Alternative

In terms of the project's stated objectives, this alternative appears to satisfy all of them. It provides a suitable plan for further progress within Riverside County, particularly in terms of increasing jobs availability. Even though it does not update the RVO study areas identified in 2003 for future planning specifications, it provides an alternate plan for future development and would also provide LUD updates, thus it does addresses the updated land use objective. It would provide updated technical data, simply by definition. And, despite increased greenhouse gas emissions, it would address the updated regulatory environment that future development within Riverside County would need to comply with (e.g., AB 32 and greenhouse gas reduction planning). Thus, it is would adequately meet the address new needs objective. Lastly, it would further the Riverside County Vision, since it proposes to greatly increase jobs in the region, helping to balance a region that traditionally has more homes than jobs, while preserving open space and the quality of life for Riverside County residents. This new economy would serve to enhance and extend the continued progress within Riverside County. In total, although this alternative meets all of the five objectives of the project, it does so while increasing growth and localized urban impacts beyond that of the proposed project or existing General Plan. For all of these reasons, the Green Economy Alternative is not deemed the preferred alternative.

Reduced Rural Villages Alternative

In terms of the project's stated objectives, this alternative does adequately meet 60% of them: It would provide LUD updates and thus addresses the updated land use objective. It would also provide updated technical data, by definition, and would address the updated regulatory environment that future development within Riverside County would need to comply with (e.g., AB 32 and greenhouse gas reduction planning) for similar reasons. Thus, it is would meet some of the objective for meeting new needs. It would not, however, provide future planning necessary to address and accommodate the new needs related to urbanizing growth pressures on rural

areas located near urban fringes. As such, it also would not accommodate further progress within Riverside County. Rather than providing plans to handle future demand for urbanizing uses within unincorporated Riverside County, this alternative actually limits further progress in terms of future development necessary to meet population growth forecast for the county. Similarly, it also would not further the Riverside County Vision, as its limits on urbanization in growing rural-fringe areas would limit, rather than enhance or extend, continued progress within Riverside County. However, because of the limitations on future urbanization inherent in this alternative, it only meets two of five of the project objectives (40%). For this reason, despite being environmentally superior, this alternative would not be an acceptable means for achieving the stated project objectives. For all of these reasons, the Reduced Rural Villages Alternative is not deemed the preferred alternative.

C. Conclusions

As the result of the data and analyses presented in Section 6.0, it was determined that two alternatives exist that would be environmentally superior to the proposed project in terms of providing a scenario for guiding ultimate build out of the Riverside County General Plan. One, however, was the No Build/No Growth Alternative, which met only a single project objective. The second environmentally superior alternative was the Reduced Rural Village Alternative. While not without significant adverse environmental impacts, this alternative addresses the widest gamut of project impacts with the fewest new significant impacts. It would not, however, meet more than two of the stated project objectives.

Thus, as a result of this alternatives analysis, it was determined that the proposed project, GPA No. 960, remained suitable as the preferred project. It would achieve all of the stated project objectives while minimizing, to the extent feasible, the significant, unavoidable environmental impacts. Further, certain beneficial aspects of the alternatives analyzed have been incorporated into the proposed project. Specifically, GPA No. 960 proposes to eliminate some of the Rural Village Study Areas in which future urbanization was found to be unsuitable, associated with too many adverse environmental effects and/or to be otherwise infeasible (for example, due to lack of water and infrastructure, topography, or seismic hazards). In this way, GPA No. 960 has incorporated impact-reducing aspects of the Reduced Rural Villages Alternative in order to ensure the most environmentally suitable project alternative goes forward for consideration by the decision-makers of Riverside County. For all of these reasons, the project, GPA No. 960, remains the preferred alternative for achieving build out of the Riverside County General Plan pursuant to the stated project objectives.

7.1 EIR Preparers and Contributors

Riverside County Transportation and Land Management Agency (TLMA), Planning Department

Juan Perez, Interim Planning Director
David L. Jones, Chief Engineering Geologist, Planning Department, Riverside County
Kristi Lovelady, Principal Planner
Cindy A. Thielman-Braun, Urban Regional Planner IV
Tamara Harrison, Urban Regional Planner IV (Resigned)
Phayvanh Nanthavongdoangsy, Urban Regional Planner III
Carolyn Syms Luna, Planning Director (Resigned)
Frank Coyle, Deputy Director (Resigned)
Jerry Jolliffe, Deputy Planning Director (Retired)
Leslie Mouriquand, County Archaeologist and Cultural Liaison (Resigned)
Mitra Mehta-Cooper, AICP, Principal Planner (Resigned)
Adam Rush, Principal Planner (Resigned)
Josh Lee, Urban Regional Planner IV (Resigned)

Riverside County TLMA, Transportation Department

Juan Perez, Director, Transportation & Land Management Agency
Kevin Tsang, Associate Civil Engineer
Richard Fairhurst, Senior Transportation Planner
Herman Basmaciyan, Consulting Engineer
Farah Khorashadi, Senior Civil Engineer (Retired)

Riverside County TLMA, Geographical Information Systems (GIS) and Demographics

JiHong McDermott, GIS Supervisor Analyst, Demographics
Phillip Kang, Senior GIS Analyst (Resigned)
Emily Lee, GIS Research Specialist I
William F. Gayk, Ph.D., Deputy Director of Administrative Services, Chief Demographer (Retired)

Riverside County Counsel

Aaron Gettis, Deputy County Counsel

Best, Best and Krieger, LLP

Michelle Ouellette, Partner
Charity B. Schiller, Partner

LSA Associates, Inc.

Lynn Calvert-Hayes, AICP, Principal
Tung-Chen Chung, PH.D, INCE, Principal
Ray Hussey, AICP, Associate
Teak-Keun Kim, PH.D, Senior Acoustical Specialist
Kent Norton, AICP, REA, Senior Environmental Planner
Kelly Czechowski, Environmental Planner
Margaret Gooding, GIS and Graphics Specialist

Atkins North America, Inc.

Michael Hendrix, Project Director, Air Quality and Climate Change
Heather Dubois, Senior Scientist
Allison J. King, Air Quality Scientist I

Technical Consultants, Copy Editing and Graphic Design

Lewis Tannenbaum, Consultant (Archival Document Preparation)
Kevin Thomas, RBF Consulting (Environmental Services Manager)
Peter Minegar, RBF Consulting (Planner)
Noelle Steele, RBF Consulting (Planner)
Hilary Potter, RBF Consulting (Copy Editor)
Jeanette Cappiello, RBF Consulting (Graphic Design)

Edwin Studor, TEP Inc. (Consulting Transporation Planner)

7.2 Persons and Agencies Consulted

The following organizations and persons were consulted in the preparation of this EIR:

Adelson, Mark. California Regional Water Quality Control Board
Avclair, Lisa. Torres-Martinez Desert Cahuilla Indians
Backs, Paula. Community Planner, Yuma Marine Corps Air Station, U.S. Marine Corps
Balys, Mark F. Member, Riverside County General Plan Advisory Committee

Blackburn, Gregor. Federal Emergency Management Agency (FEMA), Region IX, U.S. Department of Homeland Security
Blankenship, Bill. Member, Riverside County General Plan Advisory Committee
Brewer, Mark. Senior Park Planner, Riverside County Parks and Open Space Agency
Bucher, Cameron. Energy Department, Real Estate Section, Imperial Irrigation District
Burnell, Barry. Member, Riverside County General Plan Advisory Committee
Castrillo, Dennis. Disaster Assistance Programs Branch, California Emergency Management Agency
Chinaeff, Dennis. Chair, Riverside County General Plan Advisory Committee
Colunga, Raul. Community Development Department, Planning Division, City of Loma Linda
Cooper, Edward C. Riverside County Airport Land Use Commission
Corona, Steve. Member, Riverside County General Plan Advisory Committee
Criste, John. Member, Riverside County General Plan Advisory Committee
Dancy, Franklin A. Morongo Band of Mission Indians
De Salvio, Alan J. Mojave Desert Air Quality Management District
Evans, Jonathan. Center for Biological Diversity
Garcia-Tuck, Patricia. Agua Caliente Band of Cahuilla Indians
Guerin, John J.G. Principal Planner, Riverside County Airport Land Use Commission
Gutierrez, Ken. Community Development Department, Planning Division, City of Riverside
Hague, George. Member, Riverside County General Plan Advisory Committee
Hamilton, Joseph. Ramona Band of Cahuilla
Harter, Mike. Planning and Research Unit, Riverside County Sheriff Department
Hesnard, Sandy. Division of Aeronautics, California Department of Transportation
Hobday, Tracy. Strategic Planning Bureau, Riverside County Fire Department
Holmes, Elaine. Member, Riverside County General Plan Advisory Committee
Impett, Laurel L. Attorney, Shute, Mihaly and Weinberger (for Sierra Club, San Gorgonio Chapter)
Kelly, Christine. City of Chino Hills
Kirk, Tom. Member, Riverside County General Plan Advisory Committee
Larwood, Cameron. Orange County Transportation Authority
Lefebvre, Suzi. Riverside County Regional Medical Center
Leib, Jacob. Southern California Association of Governments
Lyons, Terry. General Manager, Idyllwild Water District
Macarro, Paul E. Pechanga Band of Luiseño Indians
Malacoff, Rich. City of Cathedral City
Manfredi, T.A. Marine Corps Yuma Air Station, U.S. Marine Corps
Martin, Robert. Morongo Band of Mission Indians
McCoy, Mike. Riverside Transit Agency
McKibben, Anne. Member, Riverside County General Plan Advisory Committee
Morgan, Scott. State Clearinghouse and Planning Unit, California Governor's Office of Planning and Research
Morita, Duane. City of Colton
Morse, Joel. Member, Riverside County General Plan Advisory Committee
Munoz, Rosa. Rail Crossing Engineering Section, Consumer Protection and Safety Division, California Public Utilities Commission
Nash, Sue. Friends of the Northern San Jacinto Valley
Nuaimi, Mark. City of Colton
Oesterlein, Bill. Deputy Agricultural Commissioner/Sealer, Riverside County
Ontiveros, Joseph. Soboba Band of Luiseño Indians
Osur, Michael. Deputy Director, Department of Public Health, Riverside County Community Health Agency
Pastor, Steve. Member, Riverside County General Plan Advisory Committee
Purchase, Janet. Energy Manager, Riverside County Economic Development Agency

Randall, Michelle. Member, Riverside County General Plan Advisory Committee
Reyes, Patti. Member, Riverside County General Plan Advisory Committee
Richards, Joseph A. Vice-Chair, Riverside County General Plan Advisory Committee
Robbins, Steve. Member, Riverside County General Plan Advisory Committee
Ross, Ryan. Planning, Riverside County Waste Management
Shami, Al. California Department of Toxic Substances Control
Shane, Delaine W. Metropolitan Water District of Southern California
Skipworth, Stan. Member, Riverside County General Plan Advisory Committee
Sloman, Ed. Member, Riverside County General Plan Advisory Committee
Smith, Stan. Member, Riverside County General Plan Advisory Committee
Smith, Steve. South Coast Air Quality Management District
Snell, John. Member, Riverside County General Plan Advisory Committee
Sullivan, Ronald. Member, Riverside County General Plan Advisory Committee
Sungkey Ma, Urban and Regional Planner IV, Riverside County Waste Management Department
Thompson, Tommy. Member, Riverside County General Plan Advisory Committee
Tung, Teresa. Riverside County Flood Control and Water Conservation District
Uchida, Jensen. California Public Utilities Commission
Weaver, Julia. Coachella Valley Archaeological Society
Webb, Matt. Member, Riverside County General Plan Advisory Committee

Section 8.0

Glossary and Acronyms

Section 8.0 Glossary and Acronyms

8.1 Acronyms

A

AAQS	Ambient Air Quality Standard
AB	Assembly Bill
ABOP	Antifreeze, batteries, oil and (latex) paint
Ac	Acre *(1 ac = 43,560 sf)*
ACHP	Advisory Council on Historic Properties
ACOE	(US) Army Corps of Engineers
ADP	Area Drainage Plan
ADT	Average daily traffic
AEC	Anza Electric Cooperative
AEP	Association of Environmental Professionals
AEPC	Arizona Electronic Power Cooperative
af	Acre-feet *(1 af = 325,900 gallons)*
ALUC	Airport Land Use Commission
ALUCP	Airport Land Use Compatibility Plan
ALUP	Airport Land Use Plan
ALUPH	Airport Land Use Planning Handbook
am	Ante meridiem *(i.e., morning)*
AP	Area Plan
A-P Act	Alquist-Priolo Earthquake Fault Zoning Act *(formerly the Alquist-Priolo Special Studies Zones Act)*
APS	Aboveground petroleum storage
A-P Zone	Alquist-Priolo Earthquake Fault Zone
AQ	Air quality
AQAP	Air Quality Attainment Plan
AQMP	Air Quality Management Plan
ARA	Aggregate Resource Area

B

BACT	Best available control technology
BAU	Business as usual
bcfd	Billion cubic feet per day *(1,000,000,000 cfd)*

BCP	Base Cleanup Plan
BCVRPD	Beaumont-Cherry Valley Recreation and Park District
BGS	Below ground surface
BMP	Best management practice
BNSF	Burlington Northern Santa Fe *(railroad line)*
BRAC	Base realignment and closure
BRT	Bus rapid transit

C

CAA	(Federal) Clean Air Act
CAAQS	California Ambient Air Quality Standards
CalTrans	California Department of Transportation
CalEPA	California Environmental Protection Agency
CalFire	California Department of Forestry and Fire Protection
CAMA	California – Arizona Maneuver Area
CAP	Climate Action Plan
CAPCOA	California Air Pollution Control Officers Association
CAPTAC	Comprehensive Agriculture Preserve Technical Advisory Committee
CARB	California Air Resources Board
CBSC	California Building Standards Commission
CCAA	California Clean Air Act
CCAR	California Climate Action Registry
CAS	Climate Change Adaption Strategy
CCAT	California Climate Action Team
CCR	California Code of Regulations
CCTP	Climate Change Technology Program
Cd	Cadmium
C&D	Construction and demolition
CDE	California Department of Education
CDF	California Department of Forestry and Fire Protection *(also goes by CalFire)*
CDFW	California Department of Fish and Wildlife (*formerly CDFG)*
CDMG	California Division of Mines and Geology
CEC	California Energy Commission
CEDD	California Employment Development Department
CEQA	California Environmental Quality Act
CERCLA	Comprehensive Environmental Response Compensation and Liability Act *(also known as the Superfund Act)*
CESA	California Endangered Species Act
CETAP	Community Environmental and Transportation Acceptability Program
cf	Cubic feet
CF_4	Carbon tetrafluoride
CFIP	California Forest Improvement Plan
CFR	Code of Federal Regulations
CGC	California Government Code
CGS	California Geological Survey
CH_4	Methane
CHP	California Highway Patrol

CHPO	County Historic Preservation Officer
CHRIS	California Historical Resources Information System
CHSC	California Health and Safety Code
CIC	County initiated change *(to the General Plan)*
CIP	Capital Improvement Program
CIWMB	California Integrated Waste Management Board
CIWMP	Riverside Countywide Integrated Waste Management Plan (existing)
CLOMR	Conditional Letter of Map Revision
CLOMR-F	Conditional Letter of Map Revision Based on Fill
CLUP	Comprehensive Land Use Plan
CMAGR	Chocolate Mountain Aerial Gunnery Range
CNEL	Community noise equivalent level
CNPS	California Native Plant Society
CO_2e	Carbon dioxide equivalent
CO	Carbon monoxide
COI	Certificate of Inclusion
CPHI	California Point of Historic Interest
Cr	Chromium
CRHR	California Register of Historic Resources
CSA	County Service Area
CSD	Community Service District
CVC	California Vehicle Code
CV-MSHCP	Coachella Valley Multiple Species Habitat Conservation Plan
CVWD	Coachella Valley Water District
CWA	Clean Water Act

D

dB	Decibel
dBA	A-weighted decibel
DCAP	Desert Center Area Plan
DHS	California Department of Health Services *(now known as the California Department of Public Health)*
DIF	Development impact fee
DOD	(US) Department of Defense
DOF	(US) Department of Finance
DOT	(US) Department of Transportation
DPA	Direct Protection Area
DRD	Desert Recreation District
DTSC	(California) Department of Toxic Substances Control
DU	Dwelling unit
DWR	(California) Department of Water Resources

E

EAP	Eastvale Area Plan
EBS	Environmental baseline survey
ECC	Emergency Command Center

ECS	Environmental Constraint Sheet
ECVAP	Eastern Coachella Valley Area Plan
EDA	Economic Development Agency
eGRID	Emissions and Generation Resource Integrated Database
EIA	Energy Information Administration
EIC	Eastern Information Center
EIR	Environmental Impact Report
EIS	Environmental Impact Statement
ELAP	Elsinore Area Plan
EMFAC	US-EPA's model and database for combustion emission factors
EMWD	Eastern Municipal Water District
EOC	Emergency Operations Center
EOP	Emergency Operation Plan
EPA	(US) Environmental Protection Agency
ESA	Endangered Species Act
EVRP	Evacuation and Response Plan

F

FAA	Federal Aviation Administration
FAR	Floor-to-area ratio
FAR	Federal Aviation Regulation
FCC	Family care center
FEMA	Federal Emergency Management Agency
FESA	Federal Endangered Species Act
FFA	Federal facilities agreement
FHWA	Federal Highway Administration
FIRM	Federal Insurance Rate Map
FIS	Flood Insurance Study
FCWCD	Riverside County Flood Control and Water Conservation District *(Also referred to as "Flood" or "Flood Control" or "County Flood Control")*
FMMP	(California) Farmland Mapping and Monitoring Program
FRIF	Forest Resources Investment Fund
FRA	Federal Railroad Administration
FTA	Federal Transit Administration
FUDS	Formerly used defense site

G

g	Gravity *(meaning the unit of gravitational force or acceleration)*
g	Gram
GASB	Governmental Accounting Standard Board
GHG	Greenhouse gas
GIS	Geological Information System
GPA	General Plan Amendment
GPAC	General Plan Advisory Committee
GSA	General Services Administration
GWP	Global warming potential

H

HAP	Highgrove Area Plan
HCP	Habitat Conservation Plan
HFC	Hydrofluorocarbon
HHW	Household hazardous waste
HHWE	Household Hazardous Waste Element
HMTA	Hazardous Materials Transportation Act
HOT	High-occupancy toll
HOV	High occupancy vehicle
HPS	High pressure sodium *(type of lighting)*
HRS	Hazard Ranking System
HSC	Health and Safety Code
HUD	U.S. Department of Housing and Urban Development
HWCL	Hazardous Waste Control Law
HVAC	Heating, ventilation and air condition
HVWAP	Harvest Valley / Winchester Area Plan
HWCL	Hazardous Waste Control Law
Hz	Hertz *(unit of vibration and sound)*

I

I	Interstate
IA	Implementing Agreement
IEPR	Integrated Energy Policy Report
IID	Imperial Irrigation District
IPCC	Intergovernmental Panel on Climate Change
IRP	Installation Restoration Program
IS	Initial Study
IS/NOP	Initial Study/Notice of Preparation
ISO	Insurance Service Office
IWMA	Integrated Waste Management Act

J

JARPD	Jurupa Area Recreation and Park District
JP-8	Jet fuel
JURAP	Jurupa Area Plan

K

kg	Kilogram
ksf	Thousand square feet
kV	Kilovolt

L

L_{10}, L_{50}, L_{90}	Level at which noise threshold is exceeded *X*% of the time (10%, 50%, 90%)
LAFCO	Local Agency Formation Commission
LAX	Los Angeles International Airport
L_{dn}	Day-night average equivalent *(measure of noise levels)*
LEA	Local Enforcement Agency
LEED-EB	LEED Existing Building
L_{eq}	Continuous sound level-equivalent
LFG	Landfill gas
LHMP	Local Hazard Mitigation Plan
L_{max}	Maximum A-weighted sound level
L_{min}	Minimum A-weighted sound level
LMWAP	Lake Mathews / Woodcrest Area Plan
L_N	Percentile exceedance noise levels *(For example, see L_{10}.)*
LNAP	Lakeview / Nuevo Area Plan
LOMR	Letter of Map Revision
LRA	Local Responsibility Area *(for fire hazards)*
LST	Localized Significance Threshold *(for air pollutants)*
LUD	Land Use Designation *(under the Riverside County General Plan)*
LUSTIS	Leaking Underground Storage Tank Information System

M

MJARB	March Joint Air Reserve Base
MJPA	March Joint Powers Authority
MCE	Maximum credible earthquake
MCL	Maximum contamination level *(as in water pollutant level)*
MDAB	Mojave Desert Air Basin
MDP	Master Drainage Plan
MDAQMD	Mojave Desert Air Quality Management District
MEC	Munition and Explosive of Concern
mg	Milligram
µg	Microgram
mg/L	Milligrams per liter
MLD	Most likely descendent *(referring to cultural artifact and Tribal lineage)*
MMBTU	Million British thermal unit *(measure of energy output)*
MMT	Million metric ton
MPE	Maximum probable event
mpg	Miles per gallon
mph	Miles per hour
MPO	Metropolitan Planning Organization
MRMHMP	Mineral Resources and Mineral Hazards Mapping Program
MRMPs	Mineral Resource Management Policies
MRZ	Mineral Resources Zone
MSHCP	Multiple Species Habitat Conservation Plan
MSW	Municipal solid waste
MTBE	Methyl tertiary-butyl ether *(common gasoline additive)*

MT	Metric tons
MVAP	Mead Valley Area Plan
M_w	Maximum magnitude *(measure of seismic activity)*
MWD	Metropolitan Water District of Southern California
Mwh	MegaWatt-hour

N

N_2O	Nitrous oxide
NAAQS	National Ambient Air Quality Standard
NAHC	(California) Native American Heritage Commission
NAGPRA	Native American Graves Protection and Repatriation Act
NATDAM	National Inventory of Dams
NCCP	Natural Community Conservation Planning
NDFE	Nondisposal Facility Element
NEPA	National Environmental Policy Act
NFIP	National Flood Insurance Program
NHL	National Historic Landmarks
NHPA	National Historic Preservation Act
Ni	Nickel
NIMS	National Incident Management System
NO	Nitric oxide
NO2	Nitrogen dioxide
NOC	Notice of Completion
NOP	Notice of Preparation
NOX	Nitrogen oxide *(referring generally to all compounds of nitrogen oxide)*
NPDES	National Pollutant Discharge Elimination System
NPL	National Priorities List
NRCS	Natural Resources Conservation Service
NRHP	National Register of Historic Places
NTMP	Non-Industrial Timber Management Plan
NWS	Naval Weapons Station

O

O_3	Ozone
OES	Office of Emergency Services
OHWM	Ordinary high water mark
ORV	Off-road vehicle
OPR	(California Governor's) Office of Planning and Research

P

PAP	(San Gorgonio) Pass Area Plan
PCB	Polychlorinated biphenyl
PCC	Portland cement concrete
PDP	Planning Department paleontology (study)

PG&E	Pacific Gas and Electric Company
POL	Petroleum, oil and lubricant
PRIMP	Paleontological Resource Impact Mitigation Program
PVVAP	Palo Verde Valley Area Plan
Pb	Lead
PFC	Perfluorocarbon
pm	post meridiem *(after noon, i.e., evening)*
PM-2.5	Particulate matter, fine particles - under 2.5 µm *(also written $PM_{2.5}$)*
PM-10	Particulate matter, coarse particles - between 2.5 to 10 µm *(also written PM_{10})*
ppm	Parts per million
PPV	Peak particle velocity
PRC	(California) Public Resource Code
PRPA	Paleontological Resources Preservation Act
PSD	Prevention of significant deterioration
PUC	(California) Public Utilities Code

R

RAO	Remedial Order
RAW	Removal Action Workplan
RCA	Regional Conservation Authority
RCALUC	Riverside County Airport Land Use Commission
RCBAP	Reche Canyon / Badlands Area Plan
RCCDR	Riverside County Center for Demographics Research
RCDEH	Riverside County Department of Environmental Health
RCFD	Riverside County Fire Department
RCHL	Riverside County Historical Landmark
RCIP	Riverside County Integrated Plan
RCOES	Riverside County Office of Emergency Services
RCP-10	Riverside County Projections (for Year) 2010
RCPG	Regional Comprehensive Plan and Guide
RCRA	(Federal) Resource Conservation and Recovery Act
RCRMC	Riverside County Regional Medical Center
RCWMD	Riverside County Waste Management Department
REMAP	Riverside Extended Mountain Area Plan
RHNA	Regional Housing Needs Assessment
RI/FS	Remedial Investigation and Feasibility Study
RIVTAM	Riverside County Traffic Analysis Model
RMS	Root-mean square
ROC	Reactive organic compound
ROG	Reactive organic gas
ROW	Right-of-way
RP	Responsible party
RPS	Renewable portfolio standard
RTC	Resolution trust corporation
RTP	Regional Transportation Plan
RUFMP	Riverside Unit Fire Management Plan
RVO	Rural Village Overlay

RVSA	Rural Village Study Area
RWQCB	Regional Water Quality Control Board

S

SAC	Strategic Air Command
SARA	Superfund Amendments and Reauthorization Act
SB	Senate Bill
SCAB	South Coast Air Basin
SCAG	Southern California Association of Governments
SCAQMD	South Coast Air Quality Management District
SCE	Southern California Edison
SCGC	Southern California Gas Company
SCH	State Clearinghouse
SCHWMA	Southern California Hazardous Waste Management Authority
SCS	Sustainable Communities Strategy
SEMS	Standardized Emergency Management Systems
sf	Square feet
SF_6	Sulfur hexafluoride
SFHA	Special Flood Hazard Area
SFP	School Facilities Program
SHMA	Seismic Hazards Mapping Act
SIP	State Implementation Plan
SKR-HCP	Stephens' Kangaroo Rat Habitat Conservation Plan
SLC	State Lands Commission
SMARA	State Mining and Reclamation Act
SMGB	State Mining and Geology Board
SO_2	Sulfur dioxide
SOI	Sphere of Influence
SONGS	San Onofre Nuclear Generating Station
SOP	Standard operating procedure
SOx	Sulfur oxide
SR	State Route
SRA	Source Receptor Area *(air quality)*
SRA	State Responsibility Area *(fire hazard management)*
SRRE	Source Reduction and Recycling Element
SSAB	Salton Sea Air Basin
STOLport	Short takeoff and landing airport
SWAP	Southwest Area Plan
SWPPP	Storm Water Pollution Prevention Plan
SWRCB	State Water Resource Control Board
SWTC	Southwest Transmission Cooperative

T

TAC	Toxic air contaminant
TCAP	Temescal Canyon Area Plan
TDR	Transfer of development right

TDS	Total dissolved solid
THP	Timber Harvest Plan
TL	Transmission loss
TOD	Transit-oriented development
TPZ	Timberland Production Zone
tpy	Tons per year
TRI	Toxics Release Inventory
TUMF	Transportation Uniform Mitigation Fee

U

UFC	Uniform Fire Code
UNFCCC	United Nations Framework Convention Climate Change
UP	Union Pacific *(railroad line)*
UP LA Sub	UP Los Angeles Subdivision *(railroad line)*
USACE	United States Army Corps of Engineers
USDA	United States Department of Agriculture
USEPA	United States Environmental Protection Agency
USFS	United States Forest Service
USFWS	United States Fish and Wildlife Service
USGS	United States Geological Survey
UST	Underground Storage Tank
UXO	Unexploded ordinance
UWMP	Urban Water Management Plan

V

VdB	Vibration decibel
VHFHSZ	Very High Fire Hazard Severity Zone
VMT	Vehicle miles traveled
VOC	Volatile organic compound

W

WCVAP	Western Coachella Valley Area Plan
WECS	Wind energy conversion system *(proper name for "wind turbines")*
WIMP	Wind Implementation Monitoring Program
WRC-MSHCP	Western Riverside County Multiple Species Habitat Conservation Plan
WRP	Waste Recycling Plan
WWTP	Wastewater Treatment Plan

8.2 General Plan Land Use Designation (LUD) Abbreviations

Community Development Foundation:

EDR	Estate Density Residential
VLDR	Very Low Density Residential
LDR	Low Density Residential
MDR	Medium Density Residential
MHDR	Medium High Density Residential
HDR	High Density Residential
VHDR	Very High Density Residential
HHDR	Highest Density Residential
CR	Commercial Retail
CT	Commercial Tourist
CO	Commercial Office
LI	Light Industrial
HI	Heavy Industrial
BP	Business Park
PF	Public Facilities
CC	Community Center
MUPA	Mixed Use Planning Area

Rural Community Foundation:

RC-EDR	Rural Community - Estate Density Residential
RC-VLDR	Rural Community - Very Low Density Residential
RC-LDR	Rural Community - Low Density Residential

Rural Foundation:

RR	Rural - Residential
RM	Rural - Mountainous
RD	Rural - Desert

Agriculture:

AG	Agriculture

Open Space:

OS-C	Open Space - Conservation
OS-CH	Open Space - Conservation Habitat
OS-W	Open Space - Water
OS-R	Open Space - Recreation *(or OS-REC)*
OS-RUR	Open Space - Rural
OS-MR	Open Space - Mineral Resources *(or OS-MIN)*

Overlays:

CCO	Community Center Overlay
RVO	Rural Village Overlay
CDO	Community Development Overlay

8.3 Glossary

Acre-Foot (af): An acre foot is a unit of measure and represents a volume of water that would cover an acre to a depth of one foot (43,560 cubic feet of water or approximately 326,000 gallons). Enough water is contained in an acre foot to supply the water needs of two families for one year.

Acres, Gross: The entire acreage of a site. Gross acreage is calculated to the centerline of proposed bounding streets and to the edge of the right-of-way of existing or dedicated streets.

Acres, Net: The portion of a site that can actually be built upon. The following are not included in the net acreage of a site: public or private road rights-of-way, public open-space, and flood ways.

Affordable Housing: Housing capable of being purchased or rented by a household with very low, low, or moderate income, based on a household's ability to make monthly payments necessary to obtain housing. "Affordable to low-and moderate-income households" means that at least 20 percent of the units in a development will be sold or rented to lower income households, and the remaining units to either lower or moderate income households. Housing units for lower income households must sell or rent for a monthly cost not greater than 30 percent of 60 percent of area median income. Housing units for moderate income must sell or rent for a monthly cost not greater than 30 percent of area median income.

Agriculture Preserve: An agricultural preserve defines the boundary of an area within which the County of Riverside has entered into a contract with the property owner, through a resolution of the Board of Supervisors. Only land located within an agricultural preserve is eligible for a Williamson Act contract. Preserves are regulated by rules and restrictions designated in the resolution to ensure that the land within the preserve is maintained for agricultural or open space use.

Airport Influence Area: A planning area designated by the Airport Land Use Commission around each public airport which is, or reasonably may become, affected by airport related noise, fumes, or other influence, or which is, or reasonably may become, a site for a hazard to aerial navigation.

Airport Land Use Compatibility Plan (ALUCP): Plan that protects airports from encroachment by incompatible land uses that could result in restricted operations of the airport.

Alignment: A planning term used to identify the general location of a current or future roadway. For future roadways, it is intended to describe a designated area or buffer set aside so a specific alignment (road location) can be determined as the need is established.

Alluvial Fan: A sedimentary deposit located in a topographic break such as the base of a mountain front, escarpment, or valley side, that is composed of streamflow and/or debris flow sediments and which has the shape of a fan, either fully or partially extended.

Alquist-Priolo Earthquake Fault Zoning Act of 1973: Prevents the construction of new buildings along known active faults and also requires that any building project in an active fault zone produce a geology report.

Ambient: Surrounding on all sides; used to describe measurements of existing conditions with respect to traffic, noise, air and other environments.

Ambient Air Quality Standards (AAQS): These standards measure outdoor air quality. They identify the maximum acceptable average concentrations of air pollutants during a specified period of time. These standards have been adopted at a state and federal level.

Ambient Noise: The composite of noise from all sources near and far. In this context, the ambient noise level constitutes the normal or existing level of environmental noise at a given location.

Apartment Building: A multi-unit dwelling made up of several (generally four or more) apartments, which are rented out to a family or one or more people for their exclusive use.

Aquifer: An underground, water-bearing layer of earth, porous rock, sand, or gravel, through which water can seep or be held in natural storage. Aquifers generally hold sufficient water to be used as a water supply.

Area of Statewide Significance: An area designated by the State Mining and Geology Board pursuant to PRC Section 2790 which is known to contain a deposit of minerals, the extraction of which is judged to be of prime importance in meeting future needs for minerals in a particular region (region wide) or state and which, if prematurely developed for alternate incompatible land uses, could result in the permanent loss of minerals that are of more than local or regional significance (Public Resources Code Section 2726/ Section 2727).

Arterial Highway: Medium to higher speeds (30-55 mph), medium to higher capacity (10,000-50,000 average daily trips) roadway that provides intra- and inter-community travel and access to the regional highway and freeway system. Access to community arterials should be provided at collector roads and local streets, discouraging direct access from parcels to existing arterials.

Attached: Units that are placed side-by-side so that some structural parts are touching one another, such as sharing a common wall or roof, for example.

Attainment: Compliance with state and federal ambient air quality standards within an air basin. (See "Non-attainment")

Attenuation: Reduction in the level of sound resulting from absorption by the topography, the atmosphere, distance, barriers, and other factors.

Average Daily Traffic (ADT): The average number of vehicles that travel on a given roadway in a 24-hour period (weekday).

A-weighted Decibel (dBA): A-weighted decibels are an expression of the relative loudness of sounds in air as perceived by the human ear. In the A-weighted system, the decibel values of sounds at low frequencies are reduced compared with unweighted decibels, in which no correction is made for audio frequency.

Base Flood: In any given year, a 100-year flood that has a 1 percent likelihood of occurring, and is recognized as a standard for acceptable risk.

Baseline Forecast: A prediction of future energy needs which does not take into account the likely effects of new conservation programs that have not yet been started.

Best Attainment Control Measures: A set of programs that identify and implement potentially best available control measures affecting local air quality issues.

Best Management Practice (BMP) : A policy, rule, or regulation that results in greater efficiency or benefits than from standard practices.

Bicycle Lane (Class II Facility): A corridor expressly reserved for bicycles, existing on a street or roadway in addition to any lanes for use by motorized vehicles.

Bicycle Path (Class I Facility): A paved route not on a street or roadway and expressly reserved for bicycles traversing an otherwise unpaved area. Bicycle paths may parallel roads but typically are separated from them by landscaping.

Bicycle Route (Class III Facility): A facility shared with motorists and identified only by signs, a bicycle route has no pavement markings or lane stripes.

Bike Lane: A paved area located between the travel lane(s) and shoulder (or a replacement to the shoulder) of a roadway. Bike lane locations are identified on Riverside County's Bicycle Master Plan.

Bikeways: A term that encompasses bicycle lanes, bicycle paths, and bicycle routes.

Biomass: Energy resources derived from organic matter. These include wood, agricultural waste, landfill gas, digester gas, and other living-cell material that can be burned to produce heat energy.

Biotic Community: A group of living organisms characterized by a distinctive combination of both animal and plant species in a particular habitat.

Blueline Stream: A watercourse shown as a blue line on a U.S. Geological Service topographic quadrangle map.

Brownfield: An area with abandoned, idle or under-used industrial and commercial facilities where expansion, redevelopment or reuse is complicated by real or perceived environmental contamination.

Buffer Zone: An area of land separating two distinct land uses that acts to soften or mitigate the effects of one land use on the other.

Building: A building is a resource, such as a house, barn, church, factory, hotel, or similar structure created principally to shelter or assist in carrying out any form of human activity. "Building" may also be used to refer to a historically and functionally related unit, such as a courthouse and jail or a house and barn.

Build out: Development of land to its full potential or theoretical capacity as permitted under current or proposed planning or zoning designations. (See "Carrying Capacity (3)")

CalFire (California Department of Forestry and Fire Protection): The California agency responsible for wildfire management, control and prevention on public (state) lands. In Riverside County, CalFire also functions as the Riverside County Fire Department under contract.

California Air Resources Board. The California agency responsible for air pollution control at the state level.

California Clean Air Act (CCAA): Legislation enacted in 1988 and amended in 1992 and 1996, mandating that areas which have not attained State of California ambient air quality standards for ozone, carbon monoxide, sulfur dioxide, or nitrogen dioxide to prepare plans to attain the standards by the earliest practicable date.

California Energy Commission. The state agency established by the Warren-Alquist State Energy Resources Conservation and Development Act of 1974 (Public Resources Code, Sections 25000 et seq.), responsible for energy policy.

California Department of Fish and Game (CDFG): This agency changed its name in 2012. See *California Department of Fish and Wildlife*, below.

California Department of Fish and Wildlife (CDFW): This agency maintains native fish, wildlife, plant species and natural communities for their intrinsic and ecological value and their benefits to people. This includes habitat protection and maintenance in a sufficient amount and quality to ensure the survival of all species and natural communities. The CDFW also manages the diversified use of fish and wildlife including for recreational, commercial, scientific and educational purposes.

California Environmental Quality Act (CEQA): A collection of state laws (namely, Public Resources Code Section 21000 *et seq.)* that require state and local agencies to regulate activities with consideration for environmental protection. Established in 1970, it provides an interdisciplinary framework for agencies to prevent environmental damage and contains "action-forcing" procedures to ensure that agency decision-makers take environmental factors into account.

California Power Authority: Focuses on developing the state's peak energy reserve margin and in developing renewable energy and conservation projects.

California Public Utilities Commission (CPUC): A state agency created by constitutional amendment in 1911 to regulate the rates and services of more than 1,500 privately owned utilities and 20,000 transportation companies. The major duties of the CPUC are to regulate privately owned utilities, securing adequate service to the public at rates that are just and reasonable both to customers and shareholders of the utilities; including rates, electricity transmission lines, and natural gas pipelines. The CPUC also provides electricity and natural gas forecasting, and analysis and planning of energy supply and resources.

CalTrans (California Department of Transportation): Agency responsible for the design, construction, operation and maintenance of the state highway system as well as interstates and other public freeways in California.

Capacity: The measure of a transportation facility's ability to accommodate a moving stream of people or vehicles in a given time period. Capacity and Level of Service are analyzed separately and are not simply related to each other; both must be fully considered to evaluate the overall operation of a facility.

Capital Improvement. A specific undertaking involving procurement, construction, or installation of infrastructure, facilities, or related equipment which improves, preserves, enhances or modernizes the County's provision of municipal services.

Capital Improvement Program (CIP). A plan for the implementation and financing of public facilities projects including, but not limited to, a schedule for the commencement of construction, the estimated cost of construction, and the payment of facilities benefit assessments.

Carbon Dioxide (CO_2): A chemical compound composed of one carbon and two oxygen atoms. It is present in the earth's atmosphere at a low concentration and acts as a greenhouse gas. Researchers estimate that 97% of atmospheric CO_2 created each year is from natural sources and approximately 3% is from human activities.

Carbon Footprint: A measure of the impact of human activities on the environment. The carbon footprint can be measured as the total amount of greenhouse gases and carbon dioxide emitted for a product or service within a specific geographic area.

Carbon Monoxide (CO): A colorless odorless poisonous gas formed when carbon in fuels is not burned completely. It is a byproduct of motor vehicle exhaust that can result in high concentrations of CO, particularly in local areas with heavy traffic congestion. Other sources of CO emissions include industrial processes and fuel combustion in sources such as boilers and incinerators.

Carrying Capacity: Used in determining the potential of an area to absorb development: (1) The level of land use, human activity, or development for a specific area that can be accommodated permanently without an irreversible change in the quality of air, water, land, or plant and animal habitats. (2) The upper limits of development beyond which the quality of human life, health, welfare, safety or community character within an area will be impaired. (3) The maximum level of development allowable under current zoning.

Channelization: (1) The straightening and/or deepening of a watercourse for purposes of storm-runoff control or ease of navigation. Channelization often includes lining of stream banks with a retaining material such as concrete. (2) At the intersection of roadways, the directional separation of traffic lanes through the use of curbs or raised islands that limit the paths that vehicles may take through the intersection.

Climate Change (also referred to as "Global Climate Change"). This term is sometimes used to refer to all forms of climatic inconsistency, but because the earth's climate is never static, the term is more properly used to imply a significant change from one climatic condition to another. In some cases, climate change has been used synonymously with the term, 'global warming;' scientists, however, tend to use the term in the wider sense to address uneven patterns of predicted global warming and cooling and also include natural changes in climate.

Clustered Development: Development with dwelling units placed closer together than usual, or even attached, for the purpose of retaining and maximizing open space on or near the same site.

Collector: A relatively low-speed (25-30 mph), low-volume (5,000-20,000 average daily trips) street that provides circulation within and between neighborhoods. Collectors usually serve short trips and are intended for collecting trips from local streets and distributing them to the arterial network.

Commercial Solid Waste: Solid waste originating from stores, offices, and other commercial sources but does not include construction and demolition waste nor industrial solid waste.

Community Character. The aggregate of features and traits that form the individual nature and uniqueness of a community. The constructed and natural landmarks and surroundings that cause someone to identify with a particular place or community. This character is shaped by natural, cultural, societal, and economic forces.

Community Facilities District: A special district that can issue tax-exempt bonds for the planning, design, acquisition, construction or operation of public facilities, as well as provide public services to district residents. Special tax assessments levied by the district are used to repay the bonds.

Community Noise Equivalent Level (CNEL). Refers to predominant community noise rating scale used in California for land use compatibility assessment. A CNEL value represents the average sound level for a 24-hour period based on an A-weighted decibel with upward adjustments added to account for increased noise sensitivity during the evening and night periods.

Community Park. Land with full public access intended to provide recreation opportunities beyond those supplied by neighborhood parks. Community parks are larger in scale than neighborhood parks but smaller than regional parks.

Community Service District (CSD). Provides a variety of services, subject to LAFCO approval. These services include water service, irrigation, sanitation, fire protection, and recreational uses.

Compatible Use: A land use that is capable of existing together with or adjacent to another use without conflict or ill effects.

Complete Streets: Streets that include facilities and designs that enable safe access for all users (i.e., pedestrians, bicyclists, motorists, and transit riders) of all ages and abilities with characteristics such as comprehensive, integrated, and connected network; balanced design; variety of uses and activities that create a varied streetscape; design that relates well to bordering uses and allows for continuous activity; pedestrian and biking facilities that promote safety and maximize access to bordering uses; aesthetically designed street lights that provide sufficient illumination of sidewalks; consistent landscaping that includes street trees and landscaped medians and sidewalks; sustainable design that minimizes runoff, minimizes heat island effects, responds to climatic demands, and conserves scarce resources; and well-maintained facilities.

Concurrency: Installation and operation of facilities and services needed to meet the demands of new development simultaneous with the development.

Condominium: Often consists of units in a multi-unit dwelling (i.e., an apartment or a development) where each unit is individually owned and the common areas such as hallways and recreational facilities are jointly owned (usually as "tenants in common") by all the unit owners in the building.

Congestion: Congestion is usually defined as travel time or delay in excess of that normally experienced under free flow traffic conditions. Congestion is typically accompanied by lower speeds, stop-and-go travel conditions, or queuing, such as behind ramp meters or heavily used intersections.

Congestion Management Program (CMP): A program that monitors the performance of the region's transportation system, develops programs to address near-term and long-term congestion, and better integrates transportation and land use planning.

Consistency; Consistent: Free from significant variation or contradiction. The various diagrams, text, goals, policies and programs in the general plan must be consistent with each other, not contradictory or preferential. The term "consistent with" is used interchangeably with "conformity with." The courts have held that the phrase "consistent with" means "agreement with; harmonious with." Webster defines "conformity with" as meaning harmony, agreement when used with "with." The term "conformity" means in harmony therewith or agreeable to (Sec 58 Ops.Cal.Atty.Gen. 21, 25 [1975]). California State law also requires that a general plan be internally

consistent and also requires consistency between a general plan and implementation measures such as the zoning ordinance. As a general rule, an action program or project is consistent with the general plan if, considering all its aspects, it will further the objectives and policies of the general plan and not obstruct their attainment.

Conservation Easement: An encumbrance which creates a legally enforceable land preservation agreement between a landowner and a government agency (municipality, county, state, federal) or a qualified land protection organization (often called a "land trust"), for the purposes of conservation. The property remains the private property of the landowner.

Critical Facility. Facilities housing or serving many people, that are necessary in the event of an earthquake or flood, such as hospitals, fire, police, and emergency service facilities, utility "lifeline" facilities, such as water, electricity, and gas supply, sewage disposal and communications and transportation facilities.

Cubic feet per second (cfs). A unit measure of flow expressed in cubic feet conveyed per one second.

Cubic Foot (cf *or* f^3): A common unit of measurement for volume, equal to a cube (square) one foot long on each side. Commonly used as a measure of natural gas volume; it is the amount of natural gas that fills a volume of one cubic foot under stated conditions of temperature, pressure, and water vapor. One cubic foot of natural gas has an energy content of approximately 1,000 Btus. One hundred (100) cubic feet equals one therm (100 ft^3 = 1 therm).

Cul-de-sac: A short street or alley with only a single means of ingress and egress at one end and with a large turnaround at its other end.

Cumulative Impacts: Two or more environmental effects that, when considered together, are considerable or which compound or increase other environmental impacts.

Database: A collection of information stored in an electronic format that can be searched by a computer.

Day-Night Average Noise Level (L_{dn}): A 24-hour average Leq with a 10 dBA "penalty" added to noise levels during the hours of 10:00 P.M. to 7:00 A.M. to account for increased sensitivity that people tend to have to nighttime noise. Because of this penalty, the Ldn would always be higher than its corresponding 24-hour Leq (e.g., a constant 60 dBA noise over 24 hours would have a 60 dBA Leq, but a 66.4 dBA Ldn).

dB: Decibel; a unit used to express the relative intensity of a sound as it is heard by the human ear.

dBA: The "A-weighted" scale for measuring sound in decibels; weighs or reduces the effects of low and high frequencies in order to simulate human hearing. Every increase of 10 dBA doubles the perceived loudness though the noise is actually ten times more intense.

Defensible Space: An area either natural or man-made, where material capable of allowing a fire spread unchecked has been treated, cleared, or modified to slow the rate and intensity of advancing wildfire. It is an area of increased safety for emergency fire equipment and evacuating residents and a point for fire suppression to occur.

Density, Residential: The number of permanent residential dwelling units per gross acre of land. -(See "Acres, Gross")

Density Bonus: The allocation of development rights that allows a parcel to accommodate additional square footage or additional residential units beyond the maximum for which the parcel is zoned. Under CGC Section 65915, a housing development that provides 20% of its units for lower income households, 10% of its units for very low-income households or 50% of its units for seniors, is entitled to a density bonus and other concessions.

Density, Residential: The number of permanent residential dwelling units per acre of land. Densities specified in the general plan are expressed in units per gross acre.

Density Transfer: A way of retaining open space by concentrating densities usually in compact areas adjacent to existing urbanization and utilities while leaving unchanged historic, sensitive, or hazardous areas. In some jurisdictions, for example, developers can buy development rights of properties targeted for public open space and transfer the additional density to the base number of units permitted in the zone in which they propose to develop.

Designation, Land Use (LUD): A system for classifying and designating the appropriate use of properties used in the Riverside County General Plan. The land use designations refer to the type and intensity of land uses that are compatible with a particular location and its surroundings. The land use designations (listed in General Plan Table LU-3) are defined and/or limited by the Foundation Component in which the LUD is grouped, as well as the maximum allowable residential density or non-residential building intensity (i.e., FAR).

Detention Dam, Detention Basin, Retention Pond: Detention dams are constructed to retard flood runoff, minimize the effect of sudden floods and also trap sediment (particularly as debris dams or debris basins). If the dam temporarily stores and then releases water through an outlet structure, it is referred to as a detention basin. Such basins may be planted with grass and used for open space or recreation during dry weather. When the dam allows for water to be held as long as possible, with or without the controlled release of water, it is referred to as a retention pond. When the impounded water is allowed to seep into permeable banks or gravel strata in the dam's foundation, the structure is called a water-spreading dam or dike. The main purpose of such structures is to recharge the underground water supply.

Developable Land: Land that is suitable as a location for structures and that can be developed free of hazards to, and without disruption of, or significant impact on, natural resource areas.

Development. Physical changes to land or structures that are subject to approval by the County of Riverside, or other approvals by the County of Riverside that ready land or structures for such changes.

Development Agreement. A legislatively approved contract between a jurisdiction and a person having legal or equitable interest in real property within the jurisdiction (California Government Code Section 65865 et. seq.) that "freezes" certain rules, regulations, and policies applicable to development of a property for a specified period of time, usually in exchange for certain concessions by the owner.

Development Fee. See "Impact Fee"

Disaster. An occurrence threatening the health, safety, or property of a community or larger area, generally beyond the capability of a single jurisdiction to handle. Types of disasters include man-made, natural, or war related; such as nuclear attack, earthquakes, tidal waves, floods, hurricanes, and dam failures.

Discharge. In its simplest concept, discharge means outflow; therefore, the use of this term is not restricted as to course or location, and it can be applied to describe the flow of water from a pipe or from a drainage basin. If the discharge occurs in some course or channel, it is correct to speak of the discharge of a canal or of a river.

Distribution System (Electric Utility). The substations, transformers and lines that convey electricity from high-power transmission lines to ultimate consumers.

Diversion. Any activity that results in the beneficial reuse or reduction in solid waste at the source of generation, or the diversion of solid waste from disposal through recycling, composting, and transformation.

Drainage Area. The drainage area of a stream at a specified location is that area, measured in a horizontal plane, which is enclosed by a drainage divide.

Drainage Basin. A part of the surface of the Earth that is occupied by a drainage system, which consists of a surface stream or a body of impounded surface water together with all tributary surface streams and bodies of impounded surface water.

Dry Year. A year in which rainfall is less than the long-term average.

Dwelling Unit. A room or group of rooms (including sleeping, eating, cooking, and sanitation facilities, but not more than one kitchen), that constitutes an independent housekeeping unit, occupied or intended for occupancy by one household on a long-term basis.

Earthquake. This term is used to describe both sudden slip on a fault, and the resulting ground shaking and radiated seismic energy caused by the slip, or by volcanic or magmatic activity, or other sudden stress changes in the earth.

Easement. Usually the right to use property owned by another for specific purposes or to gain access to another property. For example, utility companies often have easements on the private property of individuals to be able to install and maintain utility facilities.

Easement, Conservation. A tool for acquiring open-space with less than full-fee purchase, whereby a public agency buys only certain specific rights from the land owner. These may be positive rights (providing the public with the opportunity to hunt, fish, hike, or ride over the land) or they may be restrictive rights (limiting the uses to which the land owner may devote the land in the future.)

Elderly. Persons age 62 and older. (See "Seniors")

Emission Standard. The maximum amount of pollutant legally permitted to be discharged from a single source, either mobile or stationary.

Endangered Species. A species of animal or plant is considered to be endangered when its prospects for survival and reproduction are in immediate jeopardy from one or more causes.

Energy Conservation. Steps taken to cause less energy to be used than would otherwise be the case. These steps may involve improved efficiency, avoidance of waste, reduced consumption, etc. They may involve installing equipment (such as a computer to ensure efficient energy use), modifying equipment (such as making a boiler more efficient), adding insulation, changing behavior patterns, etc.

Energy Conservation/Efficiency. Energy efficiency is using less energy/electricity to perform the same function. Programs designed to use electricity more efficiently – doing the same with less. Energy conservation has the connotation of doing without in order to save energy rather than using less energy to do the same thing and so is not used as much today.

Environment. The physical conditions that exist within an area that will be affected by a proposed project, which in this case is the implementation of the *2000 Riverside County General Plan.* The conditions include land, air, water, minerals, flora, fauna, noise, and objects of historical or aesthetic significance.

Environmental Impact Report (EIR). A detailed statement describing and analyzing the significant environmental effects of a proposed project, and discussing ways to mitigate or avoid those effects.

Environmental Impact Statement (EIS). Under the National Environmental Policy Act, a statement on the effect of development proposals and other major actions that significantly affect the environment.

Erosion. (1) The loosening and transportation of rock and soil debris by wind, rain, or running water. (2) The gradual wearing away of the upper layers of earth.

Equivalent Sound Level (Leq). The level of steady-state sound that, in a stated time period and at a stated location, has the same sound energy as the time-varying sound (approximately equal to the average sound level). The equivalent sound level measured over a one hour period is called the hourly Leq or Leq(h).

Excavation. Any act by which soil, sand, gravel, or rock is cut into, dug, quarried, uncovered, removed, displaced, or relocated and shall include the conditions resulting there from.

Exterior Noise Levels. Noise measured at all exterior areas which are provided for group or private useable open space purposes. For CNEL levels equal to 60 decibels or greater, an acoustical analysis shall be required.

Family. (1) Two or more persons related by birth, marriage, or adoption [U.S. Bureau of the Census]. (2) An individual or a group of persons living together who constitute a bona fide single-family housekeeping unit in a dwelling unit, not including a fraternity, sorority, club, or other group of persons occupying a hotel, lodging house or institution of any kind [California].

Farmland. Refers to eight classifications of land mapped by the U.S. Department of Agriculture Soil Conservation Service. The five agricultural classifications defined below- except Grazing Land- do not include publicly owned lands for which there is an adopted policy preventing agricultural use.

Farmland of Statewide Importance. As designated by the State Farmland Monitoring and Mapping Program, Land other than Prime Farmland, which has a good combination of physical and chemical characteristics for the production of crops. It must have been used for the production of irrigated crops within the last three years.

Farmland of Local Importance. As designated by the State Farmland Monitoring and Mapping Program, Land other than Prime Farmland, Farmland of Statewide Importance, or unique Farmland that is either currently producing crops, or that has the capability of production. This land may be important to the local economy due to its productivity.

Fault. A fracture in the earth's crust forming a boundary between rock masses that have shifted.

Feasible. Capable of being accomplished in a successful manner within a reasonable time taking into account economic, environmental, social, and technological factors.

Federal Aviation Administration (FAA). The United States government agency that is responsible for insuring the safe and efficient use of the nation's airspace.

Federal Disaster Relief Act. Public Law 93-288, as amended, gives the President broad powers to supplement the efforts and available resources of state and local governments in carrying out their responsibilities to alleviate suffering and damage resulting from major (peacetime) disasters.

Federal Emergency Management Agency (FEMA). An independent federal agency established to respond to major emergencies. FEMA seeks to reduce the loss of life and protect property against all types of hazards through a comprehensive, risk-based emergency management program. In March 2003, FEMA became part of the newly created U.S. Department of Homeland Security.

Federal Energy Regulatory Commission (FERC). Regulates interstate sales and transportation of electric power and natural gas.

Federally-Mapped Floodplain. A flood-prone area that has been mapped and accepted by FEMA as the result of a flood insurance study (FIS). Mapped floodplains are used for flood insurance needs and for other regulatory purposes.

Field Act. Legislation, passed after a 1933 Long Beach earthquake that collapsed a school, which established more stringent structural requirements and standards for construction of schools than for other buildings.

Fire Hazard. A measure of the likelihood of an area burning and how it burns, developed to include speed at which a wildfire moves, the amount of heat the fire produces, and most importantly, the burning fire brands that the fire sends ahead of the flaming front.

Fiscal Impact Analysis. A projection of the direct public costs and revenues resulting from population or employment change to the local jurisdiction(s) in which the change is taking place. Enables local governments to evaluate relative fiscal merits of general plans, specific plans, or projects.

Flash flood. A sudden, violent flood, as after an intense rain.

Flood. An overflow or inundation that comes from a river or other body of water and causes or threatens damage. Any relatively high streamflow overtopping the natural or artificial banks in any reach of a stream.

Flood Control. Various activities and regulations that help reduce or prevent damages caused by flooding. Typical flood control activities include: structural flood control works (such as bank stabilization, levees, and drainage channels); acquisition of flood prone land; flood insurance programs and studies; river and basin management plans; public education programs; and flood warning and emergency preparedness activities.

Flood, 100-Year. The magnitude of a flood expected to occur on the average every 100 years, based on historical data. The 100-year flood has a 1/100, or one percent, chance of occurring in any given year.

Flood Insurance Rate Maps (FIRMs). The Federal Emergency Management Agency (FEMA) publishes maps, called Flood Insurance Rate Maps (FIRMs). The purpose of a FIRM is to show the areas in a community that have a 1 percent or greater chance of flooding in any given year. FIRMs are the result of engineering studies that are performed by engineering companies, other federal agencies, or the community and are reviewed and approved by FEMA.

Floodplain. The relatively level land area on either side of the banks of a stream regularly subject to flooding. That part of the floodplain subject to a one percent chance of flooding in any given year is designated as an "area of special flood hazard" by the Federal Insurance Administration.

Floodplain Fringe. All land between the floodway and the upper elevation of the 100-year flood.

Floodway. The channel of a river or other watercourse and the adjacent land areas that must be reserved in order to discharge the "base flood" without cumulatively increasing the water surface elevation more than one foot. No development is allowed in floodways.

Floor Area, Gross. The gross floor area of a single-story building consists of its square footage as measured from the interior face of external walls, but not including any space where the floor-to-ceiling height is less than six feet and not including courtyard spaces without ceilings that are open and unobstructed to the sky. The gross floor area of a multi-story building consists of the sum of the horizontal areas of the several floors of a building measured from the interior face of exterior walls, but not including any space where the floor-to-ceiling height is less than six feet, and not including any stairwells, shafts, or courtyard spaces. The floor area of a building, or portion thereof, not provided with surrounding exterior walls shall be the usable area under the horizontal projection of the roof or floor above. For the purposes of floor area calculation, a shaft is defined as "an interior space, enclosed by walls or construction, extending through one or more stories or basements that connects openings in successive floors, or floors and roof, to accommodate elevators, dumbwaiters, mechanical equipment, or similar devices, or to transmit light or ventilation air." (California Building Code)

Floor Area Ratio (FAR). A term utilized to measure the allowable building intensity of nonresidential structures on a site, calculated by dividing the gross floor area by the total net acres of the site. For example, on a site with 40,000 square feet of net land area, a Floor Area Ratio (FAR) of 1.0 will allow a maximum of 40,000 square feet of gross floor area to be built, whereas a FAR of 1.5 would allow 60,000 square feet of gross floor area, and a FAR of 0.5 would allow 20,000 square feet of gross floor area. Compliance of nonresidential projects covering multiple parcels with FAR building intensity restrictions may be calculated on an overall project basis rather than on individual parcels within the project; in such situations, the County of Riverside may require reciprocal use agreements, parcel mergers, or specification of property owner rights and responsibilities through Covenants, Conditions, and Restrictions or other recorded documents.

Fossil Fuel. Coal, oil and natural gas; so called because they are the remains of ancient plant and animal life.

Freeway. A high-speed, high-capacity, limited-access road serving regional and county-wide travel. Such roads are free of tolls, as contrasted with "turnpikes" or other "toll roads" now being introduced into Southern California. Freeways generally are used for long trips between major land use generators.

Fuel Modification Zone (FMZ). A wide strip of land where combustible vegetation and/or other combustible material has been removed or modified or both, with or without being partially or totally replaced with approved drought-tolerant, fire-resistant, and/or irrigated plants to provide an acceptable level of risk.

Fugitive Dust. Dust particles which are introduced into the air through certain activities such as soil cultivation, off-road vehicles, or any vehicles operating on open fields or dirt roadways.

Gallons per day (gpd). A unit measure of flow expressed in gallons conveyed in one day.

Gallons per minute (gpm). A unit measure of flow expressed in gallons conveyed in one minute.

General Aviation. The portion of civil aviation that encompasses all facets of aviation except air carriers.

General Plan. A compendium of city or county policies regarding its long-term development, in the form of goals, policies, implementation measures, and maps. The general plan is a legal document required of each local

agency by the California Government Code Section 65301 and adopted by the City Council or Board of Supervisors.

Geographic Information System (GIS). An information system for capturing, storing, analyzing, managing and presenting data which are spatially referenced.

Global Warming. An increase in the near surface temperature of the earth. Global warming has occurred in the distant past as the result of natural influences, but the term is most often used to refer to the warming predicted to occur as a result of increased emissions of greenhouse gases. Scientists generally agree that the earth's surface has warmed by about 1 degree Fahrenheit in the past 140 years, but warming is not predicted evenly around the globe. Due to predicted changes in the ocean currents, some places that are currently moderated by warm ocean currents are predicted to fall into deep freeze as the pattern changes.

Global Warming Solutions Act of 2006 (Assembly Bill 32). The California State Legislature adopted Assembly Bill (AB) 32 in 2006 to focus on reducing greenhouse gas (GHG) emissions in California. AB 32 requires the California Air Resources Board (CARB), the state agency charged with regulating state-wide air quality, to adopt rules and regulations that would achieve GHG emissions equivalent to state-wide levels in 1990 by 2020.

Grazing Land. Land on which the existing vegetation, whether grown naturally or through management, is suitable for grazing or growing of livestock. This classification does not include land previously designated as Prime Farmland, Farmland of Statewide Importance, Unique Farmland, or Farmland of Local Importance, and heavily brushed, timbered, excessively steep, or rocky lands which restrict the access and movement of livestock.

Greenbelt. A largely undeveloped area surrounding more urbanized areas, consisting of either agricultural lands, open space, conservation areas, passive parks, or very low density rural residential lands.

Greenhouse Effect. The warming of the earth's atmosphere attributed to a buildup of carbon dioxide or other gases; some scientists think that this buildup allows the sun rays to heat the earth, while making the infrared radiation atmosphere opaque to infrared radiation, thereby preventing a counterbalancing loss of heat.

Greenhouse Gas (GHG). Any gas that absorbs infrared radiation in the atmosphere. GHGs include water vapor, carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), halogenated fluorocarbons (HCFCs), ozone (O_3), perfluorinated carbons (PFCs), and hydrofluorocarbons (HFCs).

Grey Water. Washwater, such as bath, dish, and laundry water excluding toilet wastes and free of garbage grinder residues. When properly managed, grey water can be a valuable resource for planners, builders, developers and contractors because of the design and landscaping advantages of on-site treatment/management.

Groundborne Vibration. Typical groundborne vibration sources include; mining operations, including quarrying and blasting; railways and highways; industrial facilities including press shops and foundries. In extreme cases, these activities can bring about damage to local structures. It is also common for groundborne vibration to cause disturbance to occupants of structures either above or adjacent to the source.

Ground Failure. Ground movement or rupture caused by strong shaking during an earthquake. Includes landslide, lateral spreading, liquefaction, and subsidence.

Ground Shaking. The movement of the earth's surface from earthquakes or explosions. Ground motion is produced by waves that are generated by sudden slip on a fault that travel through the Earth and along its surface.

Groundwater. Water under the earth's surface, often confined to aquifers capable of supplying wells and springs.

Groundwater Recharge. The natural process of infiltration and percolation of rainwater from land areas or streams through permeable soils into water-holding rocks that provide underground storage ("aquifers").

Growth Management. The use by a community of a wide range of techniques in combination to determine the amount, type, and rate of development desired by the community and to channel that growth into designated areas. Growth management policies can be implemented through growth rates, zoning, capital improvement programs, public facilities ordinances, urban limit lines, standards for levels of service, and other programs. (See "Congestion Management Plan")

Habitat. The physical location or type of environment in which an organism or biological population lives or occurs.

Hazardous Material. A material that, because of its quantity, concentration, or physical, chemical characteristics poses a significant present or potential hazard to human health and safety or to the environment if released into the workplace or the environment. Hazardous materials include, but are not limited to, hazardous substances, hazardous waste, and any material which a handler or the administering agency has a reasonable basis for believing that it would be injurious to the health and safety of persons or harmful to the environment if released into the workplace or the environment. (California Health and Safety Code)

Hazardous Waste. A waste or combination of wastes, which because of its quantity, concentration, or physical, chemical, or infectious characteristics may either (a) cause, or significantly contribute to, an increase in mortality or an increase in serious, irreversible, or incapacitating irreversible, illness or (b) pose a substantial present or potential hazard to human health or the environment when improperly treated, stored, transported or disposed of, or otherwise managed. (California Health and Safety Code)

High Occupancy Vehicle (HOV). Any vehicle other than a driver-only automobile (e.g., a vanpool, a bus, or two or more persons to a car).

Highway. A general term usually referring to a state or federally designated urban or rural route, designed to accommodate longer trips in the region.

Historic Preservation. The preservation of historically significant structures and neighborhoods until such time as, and in order to facilitate, restoration and rehabilitation of the building(s) to a former condition.

Hourly Noise Level. The average noise level during the hour. More specifically, for airborne sound it is the mean-square A-weighted sound pressure level over the hour. The unit is the decibel (dB).

Household. All those persons (related or unrelated), who occupy a single housing unit. (See "Family")

Householder. The head of a household.

Household Hazardous Waste. Results from products purchased by the general public for household use, which, because of the quantity, concentration, physical and/or chemical characteristics, may pose a present or potential hazard to human health or the environment when improperly treated, disposed, or otherwise managed.

Households, Number of. The count of all year-round housing units occupied by one or more persons. The concept of household is important because the formation of new households generates the demand for housing.

Each new household formed creates the need for one additional housing unit or requires that one existing housing unit be shared by two households. Thus, household formation can continue to take place even without an increase in population, thereby increasing the demand for housing.

Housing Unit. The place of permanent or customary abode of a person or family. A housing unit may be a single-family dwelling, a multi-family dwelling, a condominium, a modular home, a mobile home, a cooperative, or any other residential unit considered real property under state law. A housing unit has, at least, cooking facilities, a bathroom, and a place to sleep. It also is a dwelling that cannot be moved without substantial damage or unreasonable cost. (See "Dwelling Unit" "Family" and "Household")

Impact Fee. A fee, also called a development fee, levied on the developer of a project by a city, county, or other public agency as compensation for otherwise unmitigated impacts the project will produce. Section 66000, et seq., specifies that development fees shall not exceed the estimated reasonable cost of providing the service for which the fee is charged. To lawfully impose a development fee, the public agency must verify its method of calculation and document proper restrictions on use of the fund.

Impervious Surface. Surface through which water cannot penetrate, such as roof, road, sidewalk, and paved parking lot. The amount of impervious surface increases with development and establishes the need for drainage facilities to carry the increased runoff.

Imported Water Supplies. Water supplies that lie outside the Riverside County region and require transport into the County of Riverside.

Industrial. The manufacture, production, and processing of consumer goods. Industrial is often divided into "heavy industrial" uses, such as construction yards, quarrying, and factories; and "light industrial" uses, such as research and development and less intensive warehousing and manufacturing.

Industrial Wastes. Solid, liquid or gaseous substances discharged or disposed of from an industrial, manufacturing, or commercial premise resulting from manufacturing, processing, treating, recovery, or development of natural or artificial resources of whatever nature.

Industrial Wastewater. All water carrying wastes and wastewater of the community, from any source, excluding domestic wastewater, including all wastewater from any producing, manufacturing, processing, institutional, commercial, service, agricultural, farming, all governmental uses, and all other operations of any kind or nature except domestic wastewater. These may include wastes of human origin similar to domestic wastewaters.

Industrial Solid Waste. Solid waste originating from mechanized manufacturing facilities, factories, refineries, publicly operated treatment works, and/or solid wastes placed in commercial collection bins.

Infill. Development and redevelopment of underused buildings and vacant lots in areas served by existing infrastructure. Development that channels economic growth into existing urban and suburban areas and conserves open space and agriculture at the periphery of the city.

Infill Development. Development of vacant land (usually individual lots or leftover properties) within areas that are already largely developed.

Infrastructure. Public services and facilities, such as sewage disposal systems, water supply systems, other utility systems, and roads.

Initial Study. A preliminary analysis prepared by a Lead Agency (Riverside County) determining whether an Environmental Impact Report or Negative Declaration must be prepared, and identifying the significant environmental effects to be analyzed in an Environmental Impact Report.

Institutional Uses. (1) Publicly or privately owned and operated activities such as hospitals, convalescent hospitals, intermediate care facilities, nursing homes, museums, and schools and colleges; (2) churches and other religious organizations; and (3) other nonprofit activities of a welfare, educational, or philanthropic nature that cannot be considered residential, commercial, or industrial. (See "Public and Quasi-public Facilities")

Integrated Waste Management. A process that includes effecting an overall reduction in the generation of waste and treating discarded materials as a resource, rather than as a substance of no value.

Intensity, Building. For residential uses, the actual number or the allowable range of dwelling units per acre (per gross acre, as used in this General Plan). For non-residential uses, the actual or the maximum permitted floor area ratios (FARs).

Inter-agency. Indicates cooperation between or among two or more discrete agencies in regard to a specific program.

Interior Noise Levels. Noise measured inside structures which are influenced by exterior noise and must meet a CNEL level equal to or less than 45 decibels, with the exception of certain non-residential projects where an interior CNEL noise level of 50 decibels is allowed.

Intrusive Noise. That noise which intrudes over and above the existing ambient noise at a given location. The relative intrusiveness of a sound depends upon its amplitude, duration, frequency, and time of occurrence, and tonal or informational content as well as the prevailing noise level.

Inversion Layer. A layer of warm air that traps the cooler air and any pollutants it carries, below.

Irrigated Land. Land that shows evidence of being irrigated during the year of the inventory or of having been irrigated during two or more of the last four years. Water is supplied to crops by ditches, pipes, or other conduits.

Issues. Important unsettled community matters or problems that are identified in a community's general plan and dealt with by the plan's objectives, policies, plan proposals, and implementation programs.

Jobs/Housing Balance; Jobs/Housing Ratio. The availability of affordable housing for employees. The jobs/housing ratio divides the number of jobs in an area by the number of employed residents. A ratio of 1.0 indicates a balance. A ratio greater than 1.0 indicates a net in-commute; less than 1.0 indicates a net out-commute.

Joint Powers Authority (JPA). A legal arrangement that enables two or more units of government to share authority in order to plan and carry out a specific program or set of programs that serves both units.

L10. The A-weighted sound level exceeded ten percent of the sample time. Similarly, L_{50}, L_{90} etc.

Land Banking. The purchase of land by a local government for use or resale at a later date. "Banked lands" have been used for development of low- and moderate-income housing, expansion of parks, and development of industrial and commercial centers. Federal rail-banking law allows railroads to bank unused rail corridors for future rail use while allowing interim use as trails.

Landfill Capacity. The remaining volumetric capacity of existing landfills—governed by design limitations.

Landfill Gas. Gas generated by the natural degrading and decomposition of municipal solid waste by anaerobic microorganisms in sanitary landfills. The gases produced, carbon dioxide and methane, can be collected by a series of low-level pressure wells and can be processed into a medium Btu gas that can be burned to generate steam or electricity.

Landslide. The down-slope movement of soil and/or rock.

Land Use. The occupation or use of land or water area for any human activity or any purpose defined in the general plan.

Land Use Classification. A system for classifying and designating the appropriate use of properties.

Landfill, Class I. Class I landfills are qualified to accept and manage hazardous waste. The primary objective at a Class I landfill is the protection of surface and subsurface water quality. A Class I landfill is required to be located where natural geographic features provide optimum conditions for the isolation of wastes from surface and subsurface waters.

Landfill, Class II. Waste facilities under the Class II designation are required to be located where site characteristics and containment structures isolate waste from surface and subsurface waters. Select types of hazardous materials may be deposited at Class II facilities, provided a special variance from standard hazardous waste management procedures is granted.

Landfill, Class III. Class III landfills are required to be located where adequate separation can be provided between nonhazardous solid waste and surface and subsurface waters. Class III landfills are not permitted to accept hazardous waste.

Landmark. (1) A building, site, object, structure, or significant tree, having historical, architectural, social, or cultural significance and marked for preservation by the local, state, or federal government. (2) A visually prominent or outstanding structure or natural feature that functions as a point of orientation or identification.

Lateral Spreading. Lateral movement of soil, often as a result of liquefaction during an earthquake.

Ldn. Day-Night Average Sound Level. The A-weighted average sound level for a given area (measured in decibels) during a 24-hour period with a 10 dB weighting applied to night-time sound levels. The L_{dn} is approximately numerically equal to the CNEL for most environmental settings.

Lead. A gray-white metal that is soft, malleable, and resistant to corrosion. Sources of lead resulting in concentrations in the air include industrial sources and weathering of soils followed by fugitive dust emissions.

Lead Agency. The public agency that has the principal responsibility for carrying out or approving a project. Riverside County is the Lead Agency for the *2000 Riverside County General Plan.*

Leadership in Energy and Environmental Design (LEED). A Green Building Rating System™ that encourages and accelerates global adoption of sustainable green building and development practices through the creation and implementation of universally understood and accepted tools and performance criteria.

Leq. The energy equivalent level, defined as the average sound level on the basis of sound energy (or sound pressure squared). The L_{eq} is a "dosage" type measure and is the basis for the descriptors used in current standards, such as the 24-hour CNEL used by the State of California.

Level of Service (LOS). A qualitative measure describing operational conditions within a traffic stream and the motorists' perceptions of those conditions. For example, LOS A represents free flow, almost complete freedom to maneuver within the traffic stream. LOS F represents forced flow, more vehicles are attempting to use the freeway than can be served resulting in stop and go traffic.

Level of Service (Traffic). A scale that measures the amount of traffic that a roadway or intersection can accommodate, based on such factors as maneuverability, driver dissatisfaction, and delay.

Level of Service A. Indicates a relatively free flow of traffic, with little or no limitation on vehicle movement or speed.

Level of Service B. Describes a steady flow of traffic, with only slight delays in vehicle movement and speed. All queues clear in a single signal cycle.

Level of Service C. Denotes a reasonably steady, high-volume flow of traffic, with some limitations on movement and speed, and occasional backups on critical approaches.

Level of Service D. Designates the level where traffic nears an unstable flow. Intersections still function, but short queues develop and cars may have to wait through one cycle during short peaks.

Level of Service E. Represents traffic characterized by slow movement and frequent (although momentary) stoppages. This type of congestion is considered severe, but is not uncommon at peak traffic hours, with frequent stopping, long-standing queues, and blocked intersections.

Level of Service F. Describes unsatisfactory stop-and-go traffic characterized by "traffic jams" and stoppages of long duration. Vehicles at signalized intersections usually have to wait through one or more signal changes, and "upstream" intersections may be blocked by the long queues.

Life Cycle. The period of time in which a facility runs on-line from construction completion through to the end of its useful life.

Linkage. With respect to jobs/housing balance, a program designed to offset the impact of employment on housing need within a community, whereby project approval is conditioned on the provision of housing units or the payment of an equivalent in-lieu fee. The linkage program must establish the cause-and-effect relationship between a new commercial or industrial development and the increased demand for housing.

Liquefaction. The transformation of loose, wet soil from a solid to a liquid state, often as a result of groundshaking during an earthquake.

Liquefaction. A process by which water-saturated sediment temporarily loses strength and acts as a fluid. This effect can be caused by earthquake shaking.

Lmax and Lmin. The maximum and minimum sound levels, respectively, recorded during a measurement period. When a sound meter is set to the "slow" response setting, as is typical for most community noise

measurements, the L_{max} and L_{min} values are the maximum and minimum levels recorded typically for one second periods.

Local Agency Formation Commission (LAFCO). A five- or seven-member commission within each county that reviews and evaluates all proposals for formation of special districts, incorporation of cities, annexation to special districts or cities, consolidation of districts, and merger of districts with cities. Each county's LAFCO is empowered to approve, disapprove, or conditionally approve such proposals. The LAFCO members generally include two county supervisors, two city council members, and one member representing the general public. Some LAFCOs include two representatives of special districts.

Local Coastal Program Land Use Plan. The relevant portion of a local government general plan or coastal element that details type, location, and intensity of land use, applicable resource protection and development policies, and, where necessary, implementation actions.

Low-income Household. A household with an annual income usually no greater than 80 percent of the area median family income adjusted by household size, as determined by a survey of incomes conducted by a city or a county, or in the absence of such a survey, based on the latest available eligibility limits established by the U.S. Department of Housing and Urban Development (HUD) for the Section 8 housing program.

Low-income Housing Tax Credits. Tax reductions provided by the federal and state governments for investors in housing for low-income households.

Loudness. The intensive attribute of an auditory sensation, measured in sones. Calculated loudness of a sound is obtained by a stated empirical rule from the sound spectrum in octave or third-octave bands.

Mean Sea Level. The average altitude of the sea surface for all tidal stages.

Median. The portion of the roadway that separates opposing directions of traffic. It can be raised, landscaped, or level with the roadway, with turn features added intermittently or used as a continuous left turn lane.

Median Strip. The dividing area, either paved or landscaped, between opposing lanes of traffic on a roadway.

Mercalli Intensity Scale. A subjective measure of the observed effects (human reactions, structural damage, geologic effects) of an earthquake. Expressed in Roman numerals from I to XII.

Microclimate. The climate of a small, distinct area, such as a city street or a building's courtyard; can be favorably altered through functional landscaping, architecture, or other design features.

Mined Lands. Includes the surface, subsurface, and groundwater of an area in which surface mining operations will be, are being, or have been conducted, including private ways and roads appurtenant to any such area, land excavations, workings, mining waste, and areas in which structures, facilities, equipment, machines, tools, or other materials or property which result from, or are used in, surface mining operations. (Public Resources Code Section 2729).

Minerals. Any naturally occurring chemical element or compound, or groups of elements and compounds, formed from inorganic processes and organic substances, including, but not limited to, coal, peat, and bituminous rock, but excluding geothermal resources, natural gas, and petroleum (Public Resources Code Section 2005). Gold, sand, gravel, clay, crushed stone, limestone, diatomite, salt, borate, potash, etc., are examples of minerals.

Mineral Deposit. A naturally occurring concentration of minerals in amounts or arrangement that under certain conditions may constitute a mineral resource. The concentration may be of value for its chemical or physical characteristic or for both of these properties.

Mineral Reserves. That part of the resource base which could be economically extracted or produced at the time of determination.

Mineral Resource. A concentration of naturally occurring solid, liquid, or gaseous material in or on the Earth's crust in such form and amount that economic extraction of a commodity from the concentration is currently or potentially feasible.

Minipark. Small neighborhood park of approximately one acre or less.

Mitigation Measure. A change in a project designed to avoid, minimize, rectify, reduce, or compensate for a significant environmental impact.

Mixed-Use Development. Properties on which various uses, such as office, commercial, institutional, and residential, are combined in a single building or on a single site in an integrated development project with significant functional interrelationships and a coherent physical design. A "single site" may include contiguous properties.

Mobile Source. A mobile emission source is a moving object, such as on-road and off-road vehicles, boats, airplanes, lawn equipment, and small utility engines.

Multi-family Residential. A classification of housing where multiple separate housing units are contained within one building. The most common forms are apartment buildings and town homes.

Multimodal (transportation). Generally refers to all modes of transportation, motorized and non-motorized forms, including motor vehicles, transit vehicles, trucks, and biking, pedestrian walking or jogging, and equestrian movements.

Multiple Species Habitat Conservation Plan (MSHCP). A comprehensive habitat conservation planning program that addresses multiple species' needs, including habitat, and the preservation and management/monitoring of native vegetation/species.

Multiplier Effect. The recirculation of money through the economy multiplies its impact on jobs and income. For example, money paid as salaries to industrial and office workers is spent on housing, food, clothes and other locally-available goods and services. This spending creates jobs in housing construction, retail stores (e.g., grocery and drug stores) and professional offices. The wage paid to workers in those industries is again re-spent, creating still more jobs. Overall, one job in basic industry is estimated to create approximately one more job in non-basic industry.

Municipal and Industrial Water. Water for residential and commercial uses, accounting for approximately 80 to 85 percent of water demand. Agricultural water, which has lower standards for water quality, makes up the remaining 15 to 20 percent.

Municipal Services. Services traditionally provided by local government, including water and sewer, roads, parks, schools, and police and fire protection.

Mutual Aid Agreements. Written agreement between agencies and/or jurisdictions in which they agree to assist one another upon request, by furnishing personnel and equipment.

National Ambient Air Quality Standards. The prescribed level of pollutants in the outside air that cannot be exceeded legally during a specified time in a specified geographical area.

National Environmental Policy Act (NEPA). An act passed in 1974 establishing federal legislation for national environmental policy, a council on environmental quality, and the requirements for environmental impact statements.

National Flood Insurance Program. A federal program that authorizes the sale of federally subsidized flood insurance in communities where such flood insurance is not available privately.

National Historic Preservation Act. A 1966 federal law that established a National Register of Historic Places and the Advisory Council on Historic Preservation, and that authorized grants in aid for preserving historic properties.

National Pollutant Discharge Elimination System (NPDES). A national program under Section 402 of the Clean Water Act for regulation of discharges of pollutants from point sources to waters of the United States. Discharges are illegal unless authorized by an NPDES permit.

National Register of Historic Places. The official list, established by the National Historic Preservation Act, of sites, districts, buildings, structures, and objects significant in the nation's history or whose artistic or architectural value is unique.

Natural State. The condition existing prior to development.

Negative Declaration. A written statement prepared by a Lead Agency that briefly describes the reason why a proposed project will not have a significant effect on the environment and, therefore, does not require an Environmental Impact Report.

Neighborhood. A planning area commonly identified as such in a community's planning documents, and by the individuals residing and working within the neighborhood. Documentation may include a map prepared for planning purposes, on which the names and boundaries of the neighborhood are shown.

Neighborhood Park. City- or county-owned land intended to serve the recreation needs of people living or working within one-half mile radius of the park.

Neighborhood Unit. According to one widely-accepted concept of planning, the neighborhood unit should be the basic building block of the city. It is based on the elementary school, with other community facilities located at its center and arterial streets at its perimeter. The distance from the school to the perimeter should be a comfortable walking distance for a school-age child; there would be no through traffic uses. Limited industrial or commercial would occur on the perimeter where arterials intersect. This was a model for American suburban development after World War II.

Nitrogen Oxide. Primarily consists of nitric oxides (colorless, odorless gas formed from atmospheric nitrogen and oxygen when petroleum combustion takes place under high temperatures and/or pressure) and nitrogen dioxide (a reddish-brown irritating gas formed by the combination of nitric oxide with oxygen).

Noise. Any sound that is undesirable because it interferes with speech and hearing, or is intense enough to damage hearing, or is otherwise annoying. Noise, simply, is "unwanted sound."

Noise Attenuation. Reduction of the level of a noise source using a substance, material, or surface, such as earth berm sand/or solid concrete walls.

Noise Contour. A line connecting points of equal noise level as measured on the same scale. Noise levels greater than the 60 L_{dn} contour (measured in dBA) require noise attenuation in residential development.

Noise Exposure Contours. Lines drawn about a noise source indicating constant energy levels of noise exposure. CNEL and L_{dn} are the descriptors normally utilized to describe community exposure to noise.

Non-attainment. The condition of not achieving a desired or required level of performance. Frequently used in reference to air quality. (See "Attainment")

Non-Potable Water. Water that is not acceptable for human consumption, as defined by federal, state and local drinking water standards.

Non-Renewable Natural Resources. Inanimate resources that do not increase significantly with time and whose use diminishes the total stock (e.g., minerals, fossil fuels, and fossil water).

Notice of Completion. A brief notice filed with the Office of Planning and Research by the Lead Agency, as soon as it has completed a draft Environmental Impact Report.

Notice of Determination. A brief notice filed by a public agency after it approves or determines to carry out a project.

Notice of Hearing. A legal document announcing the opportunity for the public to present their views to an official representative or board of a public agency concerning an official action pending before the agency.

Notice of Preparation. A brief notice sent by a Lead Agency notifying Responsible, Trustee, and involved federal agencies that it plans to prepare an Environmental Impact Report for a project.

Off-Peak. Periods of relatively low system demands.

On-Peak Energy. Energy supplied during periods of relatively high system demand as specified by the supplier.

Open-Space Land. Any parcel or area of land or water that is essentially unimproved and devoted to an open-space use for the purposes of (1) the preservation of natural resources, (2) the managed production of resources, (3) outdoor recreation, or (4) public health and safety.

Ordinance. A law or regulation set forth and adopted by a governmental authority, usually a city or county.

Outdoor Advertising Structure. Any device used or intended to direct attention to a business, profession, commodity, service, or entertainment conducted, sold, or offered elsewhere than upon the lot where such device is located.

Outdoor Recreation Use. A privately or publicly owned or operated use providing facilities for outdoor recreation activities.

Overdraft. The condition of a groundwater basin or sub-basin in which the amount of water withdrawn by pumping (or by other means such as groundwater discharge to wetlands or streams) exceeds the amount of water that recharges the basin over a period of years, during which the water supply conditions approximate average conditions.

Overlay. A land use designation on the General Plan Land Use Map, or a zoning designation on a zoning map, that modifies the basic underlying designation in some specific manner.

Ozone. A pungent, colorless, toxic gas. Close to the earth's surface, it is produced photochemically from hydrocarbons, oxides of nitrogen and sunlight and is a major component of smog. At very high altitudes it protects the earth from harmful ultraviolet radiation.

Ozone Precursors. There are several chemical steps in creating ozone. Ozone precursors are chemicals that lead to the eventual creation of ozone. Ozone precursors occur either naturally or as a result of human activities, such as the use of combustion engines in cars.

Paratransit. An alternative mode of flexible passenger transportation that does not follow fixed routes or schedules. Typically vans or mini-buses are used to provide paratransit service, but also share taxis and jitneys are important providers.

Parcel. A lot in single ownership or under single control, usually considered a unit for purposes of development. Park Land; Parkland: Land that is publicly owned or controlled for the purpose of providing parks, recreation, or open-space for public use.

Parking Area, Public. An open area, excluding a street or other public way, used for the parking of automobiles and available to the public, whether for free or for compensation.

Parking Management. An evolving TDM technique designed to obtain maximum utilization from a limited number of parking spaces. Can involve pricing and preferential treatment for HOVs, non-peak period users, and short-term users. (See "High Occupancy Vehicle" and "Transportation Demand Management")

Parking Ratio. The number of parking spaces provided per 1,000 square of floor area (e.g., 2:1 or "two per thousand.")

Parking, Shared. A public or private parking area used jointly by two or more uses.

Parking Space, Compact. A parking space (usually 7.5 feet wide by 16 feet long when perpendicular to a driveway or aisle) permitted in some localities on the assumption that many modern cars are significantly smaller, and require less room, than a standard automobile. A standard parking space, when perpendicular to a driveway or aisle, is usually 8.5 feet wide by 18 feet long.

Parks. Open-space lands whose primary purpose is recreation. (See "Open-Space Land," "Community Park," and "Neighborhood Park.")

Parkway. An expressway or freeway designed for non-commercial traffic only; usually located within a strip of landscaped park or natural vegetation.

Parkway Strip. A piece of land located between the rear of a curb and the front of a sidewalk, usually used for planting low ground cover and/or street trees, also known as "planter strip."

Particulate Matter (PM). Atmospheric particulate made up of finely divided solids or liquids such as soot, dust, aerosols, fumes and mists. Commonly classified into two categories, PM_{10} (particles between 2.5 and 10 micrometers in length) and $PM_{2.5}$ (particles less than 2.5 micrometers in length).

Peak Delivery. The delivery of water during a peak demand event such as a peak day.

Peak Hour. The time period during which the greatest demand occurs on the transportation or infrastructure system in the morning and early afternoon, also known as "rush hour."

Peak Load. The highest electrical demand within a particular period of time. Daily electric peaks on weekdays occur in late afternoon and early evening. Annual peaks occur on hot summer days.

Performance Standards. Zoning regulations that permit uses based on a particular set of standards of operation rather than on particular type of use. Performance standards provide specific criteria limiting noise, air pollution, emissions, odors, vibration, dust, dirt, glare, heat, fire hazards, wastes, traffic impacts, and visual impact of a use.

Permeability (groundwater). Ability of a rock or unconsolidated deposit to transmit water through spaces that connect between grains. The size and shape of the spaces controls how well water transmits, or "flows."

Pervious Surface. A ground cover through which water can penetrate at a rate comparable to that of water through undisturbed soils.

Photovoltaic Cell. A semiconductor that converts light directly into electricity.

Plan Line. A precise line that establishes future rights-of-way along any portion of an existing or proposed street or highway and which is depicted on a map showing the streets and lot line or lines and the proposed right-of-way lines, and the distance thereof from the established centerline of the street or highway, or from existing or established property lines.

Planning Area. The area directly addressed by the general plan. A city's planning area typically encompasses the city limits and potentially annexable land within its sphere of influence.

Planning Commission. The Riverside County Planning Commission, a five-member body appointed by the Board of Supervisors to perform various development review and planning functions and make recommendations to the Board, in accordance with Riverside County Ordinance No. 348 and California Government Code Section 65100.

Pollution, Non-Point. Sources for pollution that are less definable and usually cover broad areas of land, such as agricultural land with fertilizers that are carried from the land by runoff, or automobiles.

Pollution, Point. In reference to water quality, a discrete source from which pollution is generated before it enters receiving waters, such as a sewer outfall, a smokestack, or an industrial waste pipe.

Poverty Level. As used by the U.S. Census, families and unrelated individuals are classified as being above or below the poverty level based on a poverty index that provides a range of income cutoffs or "poverty thresholds" varying by size of family, number of children, and age of householder. The income cutoffs are updated each year to reflect the change in the Consumer Price Index.

Pro Rata. Refers to the proportionate distribution of something to something else or to some group, such as the cost of infrastructure improvements associated with new development apportioned to the users of the infrastructure on the basis of projected use.

Private Airport. Any airport that allows use of its facilities only by the owner or his invitees.

Private Road/Private Street. Privately owned (and usually privately maintained) motor vehicle access that is not dedicated as a public street. Typically the owner posts a sign indicating that the street is private property and limits traffic in some fashion. For density calculation purposes, some jurisdictions exclude private roads when establishing the total acreage of the site; however, aisles within and driveways serving private parking lots are not considered private roads.

Program EIR. An Environmental Impact Report that may be prepared on a series of actions that can be characterized as one large project and are related either geographically; as logical parts in the chain of contemplated actions; in connection with issuance of rules, regulations, plans, or other general criteria to govern the conduct of a continuing program; or as individual activities carried out under the same authorizing statutory or regulatory authority and having generally similar environmental effects that can be mitigated in similar ways. This EIR is a Program EIR.

Proposition 13. An initiative amendment to the California Constitution passed in June 1978. Tax rates on secured property are restricted to no more than one percent of "full cash value." Proposition 13 also defines assessed value and requires a two-thirds vote to change existing or levy new taxes.

Public and Quasi-public Facilities. Institutional, academic, governmental and community service uses, either owned publicly or operated by non-profit organizations, including private hospitals and cemeteries.

Public Airport. Any airport that offers the use of its facilities to the public in general, without prior notice and without specific invitation or clearance. An airport proprietor or operator may preclude use by a size or type of aircraft for which the facilities are not adequate without altering the public status of the airport.

Public Services. See "Municipal Services"

Public Utility Regulatory Policy Act (PURPA). 1978. Federal legislation requires utilities to buy electric power from private "qualifying facilities," at an avoided cost rate. This avoided cost rate is equivalent to what it would have otherwise cost the utility to generate or purchase that power themselves. Utilities must further provide customers who choose to self-generate a reasonably priced back-up supply of electricity.

Rangeland. Open grazing land.

Reactive Organic Gases (ROG). Reactive organic gases are photochemically reactive and are composed of non-methane hydrocarbons. These gases contribute to the formation of smog.

Reasonable Attainment Control Measures (RACMs). The Environmental Protection Agency requirement for air quality attainment plans to: a) implement all reasonably available control measures; and b) do it as expeditiously as practicable.

Reclaimed Water. Tertiary-treated recycled water from the three-stage treatment of municipal wastewater and is allowable for full-body human contact but not for direct human consumption.

Reclamation. The reuse of resources, usually those present in solid wastes or sewage.

Reclamation (Mining). The combined process of land treatment that minimizes water degradation, air pollution, damage to aquatic or wildlife habitat, flooding, erosion, and other adverse effects from surface mining operations, including adverse surface effects incidental to underground mines, so that mined lands are reclaimed to a usable condition which is readily adaptable for alternate land uses and create no danger to public health or safety. The process may extend to affected lands surrounding mined lands, and may require backfilling, grading, resoiling, revegetation, soil compaction, stabilization, or other measures (Public Resources Code Section 2733).

Reconstruction. As used in historic preservation, the process of reproducing by new construction the exact form and detail of a vanished structure, or part thereof, as it appeared during a specific period of time. Reconstruction is often undertaken when the property to be reconstructed is essential for understanding and interpreting the value of an historic district and sufficient documentation exists to insure an exact reproduction of the original.

Recreation, Active. A type of recreation or activity that requires the use of organized play areas including, but not limited to, softball, baseball, football and soccer fields, tennis and basketball courts and various forms of children's play equipment.

Recreation, Passive. Type of recreation or activity that does not require the use of organized play areas and can include use of unimproved recreation areas, such as trails and open space.

Recycled Water. Water available from the agency's recycled water facilities, which may include a combination of treated wastewater, intercepted surface and subsurface stream flows, groundwater and other waters including potable water. Tertiary-treated recycled water can be used for virtually all nonpotable applications such as urban landscapes, agriculture, and industrial uses, including structural and nonstructural fire fighting. Irrigating with recycled water is making use of a valuable resource that would otherwise be disposed.

Recycling. The process of collecting, sorting, cleansing, treating, and reconfiguring materials that would otherwise become solid waste, and returning them to the economic mainstream in the form of raw material for new, reused, or reconstituted products which meet the quality standards necessary to be used in the marketplace. Recycling does not include transformation.

Redevelop. To demolish existing buildings; or to increase the overall floor area existing on a property; or both; irrespective of whether a change occurs in land use.

Regional. Pertaining to activities or economies at a scale greater than that of a single jurisdiction, and affecting a broad geographic area.

Regional Park. A park typically 150-500 acres in size focusing on activities and natural features not included in most other types of parks and often based on a specific scenic or recreational opportunity.

Regional Transportation Plan. A plan developed by Southern California Association of Governments (SCAG) to meet the region's long-term mobility needs, better connect transportation and land use policy decisions, and create a transportation network that will serve the people of this region.

Renewable Energy. Resources that constantly renew themselves or that are regarded as practically inexhaustible. These include solar, wind, geothermal, hydro, and wood. Although particular geothermal formations can be depleted, the natural heat in the Earth is a virtually inexhaustible reserve of potential energy. Renewable resources

also include some experimental or less-developed sources such as tidal power, sea currents, and ocean thermal gradients.

Reservoir. A pond, lake, or basin, either natural or artificial, for the storage, regulation, and control of water.

Residential, Multiple Family. Usually three or more dwelling units on a single site, which may be in the same or separate buildings.

Residential, Single-family. A single dwelling unit on a building site.

Residential Solid Waste. Solid waste generated in single-family or multi-family dwellings.

Response Time. Calculated by adding the call-time (time it takes dispatcher to reach an emergency service provider), reflex time (time it takes service provider to put on equipment, leave the station, and travel to fire station), and travel time (time it takes to reach the emergency location).

Responsible Agency. A public agency that proposes to carry out or approve a project for which a Lead Agency is preparing or has prepared an Environmental Impact Report.

Retrofit. To add materials and/or devices to an existing building or system to improve its operation, safety, or efficiency. Buildings have been retrofitted to use solar energy and to strengthen their ability to withstand earthquakes, for example.

Rezoning. An amendment to the map and/or text of a zoning ordinance to effect a change in the nature, density, or intensity of uses allowed in a zoning district and/or on a designated parcel or land area.

Richter Scale. A measure of the size or energy release of an earthquake at its source. The scale is logarithmic; the wave amplitude of each number on the scale is 10 times greater than that of the previous whole number.

Right-of-way. A strip of land occupied or intended to be occupied by certain transportation and public use facilities, such as roads, railroads, and utility lines.

Riverside County Transportation Analysis Model (RIVTAM). A zone-based travel demand model which was developed as a sub-regional model based on the Southern California Association of Government's 2008 Region Transportation Plan travel demand forecasting model, focusing on Riverside County.

Road (Private). Any road which has not been declared or accepted for public use and/or county maintenance by the County of Riverside.

Road (Public). Any road improved to Riverside County standards with a dedicated right-of-way that has been granted and accepted into the Riverside County system of maintained public roads and approved for public use.

Sanitary Landfill. The controlled placement of refuse within a limited area, followed by compaction and covering with a suitable thickness of earth and other containment material.

Sanitary Sewer. A system of subterranean conduits that carries refuse liquids or waste matter to a plant where the sewage is treated, as contrasted with storm drainage systems (that carry surface water) and septic tanks or leech fields (that hold refuse liquids and waste matter on-site). (See "Septic System")

Santa Ana Winds. Warm, dry winds that blow from the east or northeast (offshore) occurring predominantly between the months of December and February. The winds develop when a region of high pressure builds over the Great Basin (the high plateau east of the Sierra Mountains and west of the Rocky Mountains including most of Nevada and Utah) and move locally across the Mojave Desert and then over and through passes in the San Gabriel, San Bernardino and San Jacinto Mountains.

Seismic. Caused by or subject to earthquakes or earth vibrations.

Scenic Corridor. The visible land outside of the highway right-of-way or "the view from the road" which can be subjected to the scenic corridor protection measures.

Scenic Highway. A highway may be designated as 'scenic' by CalTrans or the County of Riverside depending upon how much of the natural landscape can be seen by travelers, the scenic quality of the landscape, and the extent to which development intrudes upon the traveler's enjoyment of the view.

Scenic Resources. The objective and subjective visual elements of a unique or irreplaceable landscape, including rewarding views of vegetation, topography, geological formations, and historical sites.

Scenic Viewshed. An aesthetic resource with views of a scenic vista or key point(s) of interest.

Sensitive Receptors. Sensitive receptors are defined as land uses that typically accommodate sensitive population groups such as long term health care facilities, rehabilitation centers, retirement homes, convalescent homes, residences, schools, childcare centers, and playgrounds.

Septic System. A sewage-treatment system that includes a settling tank through which liquid sewage flows and in which solid sewage settles and is decomposed by bacteria in the absence of oxygen. Septic systems are often used for individual-home waste disposal where an urban sewer system is not available. (See "Sanitary Sewer")

Settlement. (1) The drop in elevation of a ground surface caused by settling or compacting. (2) The gradual downward movement of an engineered structure due to compaction. Differential settlement is uneven settlement, where one part of a structure settles more or at a different rate than another part.

Sidewalk. A paved pedestrian walkway, generally located within the parkway.

Siltation. (1) The accumulating deposition of eroded material. (2) The gradual filling in of streams and other bodies of water with sand, silt, and clay.

Single-family Dwelling, Attached. A dwelling unit occupied or intended for occupancy by only one household that is structurally connected with at least one other such dwelling unit.

Single-family Dwelling, Detached. A dwelling unit occupied or intended for occupancy by only one household that is structurally independent from any other such dwelling unit or structure intended for residential or other use. (See "Family.")

Site. A parcel of land used or intended for one use or a group of uses and having frontage on a public or an approved private street. A lot.

Smog. A combination of smoke, ozone, hydrocarbons, nitrogen oxides, and other chemically reactive compounds which, under certain conditions of weather and sunlight, may result in a murky brown haze that causes adverse health effects. The primary source of smog in California is motor vehicles.

Solid Waste. Any unwanted or discarded material that is not a liquid or gas. Includes organic wastes, paper products, metals, glass, plastics, cloth, brick, rock, soil, leather, rubber, yard wastes and wood, but does not include sewage and hazardous materials. Organic wastes and paper products comprise about 75 percent of typical urban solid waste.

Sound Level. The quantity in decibels measured by a sound-level meter satisfying requirements of the American National Standard Specifications for Sound Level Meters S1.4-1971. Sound level is the frequency weighted sound pressure level obtained with the standardized dynamic characteristic "fast" or "slow" and weighting A or C; unless indicated otherwise, the A-weighting is understood. The unit of any of the sound levels is the decibel. The A-weighting makes the sound-level meter relatively less sensitive to low-frequency sound, somewhat in the way the ear is progressively less sensitive to sounds of frequency below kHz. The C-weighting makes the sound-level meter relatively less sensitive to low-frequency sound, somewhat in the way the ear is progressively less sensitive to sounds of frequency below kHz. The C-weighting gives the sound-level meter a constant sensitivity in the frequency range 32 to 8000 Hz.

Source Reduction. Refers to any action which causes a net reduction in the generation of solid waste and includes, but is not limited to, replacing disposable materials and products with reusable materials and products, reducing packaging and increasing the efficient use of materials.

South Coast Air Basin (SCAB). An air basin is a geographic area that exhibits similar meteorological and geographic conditions. California is divided into fifteen air basins to assist with the statewide regional management of air quality issues. The SCAB is bounded on the west by the Pacific Ocean, San Gorgonio Pass to the east, San Diego County to the south and Transverse mountains to the north.

South Coast Air Quality Management District (SCAQMD). The SCAQMD is the regulatory agency responsible for developing air quality plans, monitoring air quality, and reporting air quality data for the SCAB and SSAB.

Southern California Association Of Governments (SCAG). Serves as the forum for decision-making on regional issues such as growth, transportation, land use, the economy, the environment, and criminal justice in the San Diego region. SANDAG is governed by a Board of Directors composed of mayors, council members, and supervisors from each of the San Diego region's 19 local governments, as well as ex officio members from Caltrans, Indian tribes, and Mexico.

Specific Plan. A tool authorized by Government Code Section 65450, et seq. for the systematic implementation of the General Plan for a defined portion of a community's planning area. A specific plan must specify in detail the land uses, public and private facilities needed to support the land uses, phasing of development, standards for the conservation, development, and use of natural resources, and a program of implementation measures, including financing measures.

Sphere of Influence. The probable physical boundaries and service area of a local agency, as determined by the Local Agency Formation Commission of the County.

Splay. Spread wide and outward. A hazardous area along a fault.

Standards. (1) A rule or measure establishing a level of quality or quantity that must be complied with or satisfied. Government Code Section 65302 requires that general plans spell out the objectives, principles, "standards" and proposals of the general plan. Examples of standards might include the number of acres of park land per 1,000 population that the community will attempt to acquire and improve, or the "traffic Level of Service" (LOS) that the plan hopes to attain. (2) Requirements in a zoning ordinance that govern building and development as distinguished from use restrictions - for example, site-design regulations such as lot area, height limit, frontage, landscaping and floor area ratio.

Statement of Overriding Consideration. A written explanation prepared by a public agency that explains why it approved a project, despite the presence of significant, unavoidable environmental impacts.

State Water Project. A water storage and delivery system of reservoirs, aqueducts, power plants, and pumping plants, which extends over two-thirds of California, and delivers water from the Sierra Nevada Mountains and Sacramento Delta South to Central and Southern California water agencies.

Stormwater. Precipitation from rain or snow that accumulates in a natural or man-made watercourse or conveyance system.

Streets, Local. See "Streets, Minor"

Streets, Major. The transportation network that includes a hierarchy of freeways, arterials, and collectors to service through traffic.

Streets, Minor. Local streets not shown on the Circulation Plan, Map, or Diagram, whose primary intended purpose is to provide access to fronting properties.

Streets, Through. Streets that extend continuously between other major streets in the community.

Structure. Anything constructed or erected that requires location on the ground (excluding swimming pools, fences, and walls used as fences).

Subregional. Pertaining to a portion of a region.

Subdivision. The division of a tract of land into defined lots, either improved or unimproved, which can be separately conveyed by sale or lease, and which can be altered or developed. "Subdivision" includes a condominium project as defined in Section 1350 of the California Civil Code and a community apartment project as defined in Section 11004 of the Business and Professions Code.

Subsidence. The sudden sinking or gradual downward settling and compaction of soil and other surface material with little or no horizontal motion. Subsidence may be caused by a variety of human and natural activity, including earthquakes. (See "Settlement")

Substandard Housing. Residential dwellings that, because of their physical condition, do not provide safe and sanitary housing.

Sulfur Dioxide. A colorless, odorless, pungent, irritating gas formed primarily by the combustion of sulfur-containing fossil fuels.

Surface Mining and Reclamation Act (SMARA). State law that authorizes and directs local agencies to adopt ordinances establishing procedures for the review and approval of reclamation plans and the issuance of permits to conduct surface mining operations.

Surface Runoff. The amount of rainfall water that does not percolate into the ground prior to flowing by gravity to surface storage.

Surface Rupture. The breakage of ground along the surface trace of a fault caused by the intersection of the fault surface area ruptured in an earthquake with the Earth's surface.

Surface Water. Water that flows in streams and rivers and in natural lakes, in wetlands, and in reservoirs constructed by humans.

Sustainability. Community use of natural resources in a way that does not jeopardize the ability of future generations to live and prosper.

Sustainable Development. Development that maintains or enhances economic opportunity and community well-being while protecting and restoring the natural environment upon which people and economies depend. Sustainable development meets the needs of the present without compromising the ability of future generations to meet their own needs. (Source. Minnesota State Legislature)

Tax Increment. Additional tax revenues that result from increases in property values within a redevelopment area. State law permits the tax increment to be earmarked for redevelopment purposes but requires at least 20 percent to be used to increase and improve the community's supply of very low- and low-income housing.

Telecommuting. An arrangement in which a worker is at home or in a location other than the primary place of work, and communicates with the workplace and conducts work via wireless or telephone lines, using modems, fax machines, or other electronic devices in conjunction with computers.

Threshold Capacity. The maximum capacity a road can carry at an acceptable level of service (defined by Riverside County policy as LOS A through D). Traffic volumes above this threshold indicate an unacceptable level of service (LOS E, F).

Tiering. Refers to the concept of multi-tiered approach to preparing Environmental Impact Reports. The first-tier Environmental Impact Report covers general issues in a broader program-oriented analysis. Subsequent tiers incorporate by reference the general discussion from the broader Environmental Impact Report, while primarily concentrating on the issues specific to the action being evaluated.

Total Response Time. The total amount of time it takes a unit to reach the incident from the time of the call. Total Response Time can be calculated by adding the Dispatch Time, Turnout Time, and Travel Time.

Traffic Model. A mathematical representation of traffic movement within an area or region based on observed relationships between the kind and intensity of development in specific areas. Many traffic models operate on the theory that trips are produced by persons living in residential areas and are attracted by various non-residential land uses. (See "Trip")

Trail. A marked, graded, or paved non-motorized path, typically removed from vehicular roadways that are primarily recreational in nature. Trails can also serve as alternative modes of transportation. Trail characteristics vary depending upon location and type of use. Trails within or adjacent to open space or MSHCP preserves are

guided by ecological principles and the prevailing MSHCP, which require resources protection first, with active recreational as subservient uses.

Transfer of Development Rights. Also known as "Transfer of Development Credits," a program that can relocate potential development from areas where proposed land use or environmental impacts are considered undesirable (the "donor" site) to another ("receiver") site chosen on the basis of its ability to accommodate additional units of development beyond that for which it was zoned, with minimal environmental, social, and aesthetic impacts.

Transit. The conveyance of persons or goods from one place to another by means of a local, public transportation system.

Transit, Public. A system of regularly scheduled buses and/or trains available to the public on a fee-per-ride basis. Also called "Mass Transit."

Transit-dependent. Refers to persons unable to operate automobiles or other motorized vehicles, or those who do not own motorized vehicles. Transit-dependent citizens must rely on transit, paratransit, or owners of private vehicles for transportation. Transit-dependent citizens include the young, the handicapped, the elderly, the poor, and those with prior violations in motor vehicle laws.

Transit-oriented Development (TOD). A mixed-use community within an average 2,000-foot walking distance of a transit stop and core commercial area. TODs mix residential, retail, office, and public uses in a walkable environment, making it convenient for residents and employees to travel by transit, bicycle, foot, or car.

Transit Nodes. A subcategory of the Village classification, includes sites within walking distance - approximately ¼ mile – of future rapid transit stations. Served by either express bus or rail service, Transit Node areas are planned as diverse, mixed-use areas with a range of residential, retail, and where appropriate, employment-generating land uses (e.g., office/professional or light industrial) as well as parks and civic spaces.

Transit Service Types.

- Fixed - Service that follows a set route and schedule, including urban and suburban rail and bus service.
- Demand Responsive - Service that does not operate on a set schedule, but is available to pick up passengers when they call for service. This is often in a van or smaller bus that picks up multiple passengers at a time.
- Paratransit - Transportation services such as car pooling, van pooling, taxi service, and dial-a-ride programs.

Transitional Housing. Shelter provided to the homeless for an extended period, often as long as 18 months, and generally integrated with other social services and counseling programs to assist in the transition to self-sufficiency through the acquisition of a stable income and permanent housing.

Transportation Demand Management (TDM). A strategy for reducing demand on the road system by reducing the number of vehicles using the roadways and/or increasing the number of persons per vehicle. TDM attempts to reduce the number of persons who drive alone on the roadway during the commute period and to increase the number in carpools, vanpools, buses and trains, walking and biking. TDM can be an element of TSM (see below).

Transportation Systems Management (TSM). A comprehensive strategy developed to address the problems caused by additional development, increasing trips, and a shortfall in transportation capacity. Transportation Systems Management focuses on more efficiently utilizing existing highway and transit systems rather than expanding them. TSM measures are characterized by their low cost and quick implementation time frame, such as computerized traffic signals, metered freeway ramps, and one-way streets.

Trip. A one-way journey that proceeds from an origin to a destination via a single mode of transportation; the smallest unit of movement considered in transportation studies. Each trip has one "production end" (or origin - often from home, but not always), and one "attraction end" (destination). (See "Traffic Model.")

Trip Generation. The dynamics that account for people making trips in automobiles or by means of public transportation. Trip generation is the basis for estimating the level of use for a transportation system and the impact of additional development or transportation facilities on an existing, local transportation system. Trip generations of households are correlated with destinations that attract household members for specific purposes.

Truck Route. A path of circulation required for all vehicles exceeding set weight or axle limits, a truck route follows major arterials through commercial or industrial areas and avoids sensitive areas.

Trustee Agency. A state agency with legal jurisdiction over natural resources held in trust for the people of the state, and which are affected by a project.

Uniform Building Code (UBC). A national, standard building code that sets forth minimum standards for construction.

Urban. Of, relating to, characteristic of, or constituting a city. Urban areas are generally characterized by moderate and higher density residential development (i.e., three or more dwelling units per acre), commercial development, and industrial development, and the availability of public services required for that development, specifically central water and sewer, an extensive road network, public transit, and other such services (e.g., safety and emergency response). Development not providing such services may be "non-urban" or "rural" (See "Urban Land Use"). CEQA defines "urbanized area" as an area that has a population density of at least 1,000 persons per square mile (Public Resources Code Section 21080.14(b)).

Urban Design. The attempt to give form, in terms of both beauty and function, to selected urban areas or to whole cities. Urban design is concerned with the location, mass, and design of various urban components and combines elements of urban planning, architecture, and landscape architecture.

Urban Land Use. Residential, commercial or industrial land use in areas where urban services are available.

Urban Services. Utilities (such as water, gas, electricity and sewer) and public services (such as police, fire, schools, parks and recreation) provided to an urbanized or urbanizing area.

Urban / Wetlands Interface. The area where structures and other human occupancy development meet or intermingle with undeveloped wildland or vegetation.

U.S. Fish and Wildlife Service (USFWS). A bureau within the Department of the Interior with the mission to work with others to conserve, protect and enhance fish, wildlife and plants and their habitats for the continuing benefit of the American people.

Unincorporated Area. Land located outside the city limits.

Unique Farmland. As designated by the State Farmland Monitoring and Mapping Program, Land which does not meet the criteria for Prime Farmland or Farmland of Statewide Importance that is currently used for the production of specific high economic value crops. It has the special combination of soil quality, location, growing season and moisture supply needed to produce sustained high quality or high yields of a specific crop when treated and managed according to current farming methods. Examples of such crops may include oranges, olives, avocados, rice, grapes and cut flowers.

Utility. A regulated entity, which exhibits the characteristics of a natural monopoly. For the purposes of electric industry restructuring, "utility" refers to the regulated, vertically integrated electric company. "Transmission utility" refers to the regulated owner/operator of the transmission system only. "Distribution utility" refers to the regulated owner/operator of the distribution system, which serves retail customers.

Utility Corridors. Rights-of-way or easements for utility lines on either publicly or privately owned property. (See "Right-of-way" or "Easement")

Vegetation Community. A group of plants that tend to occur together in consistent definable groups based on typical constituents.

Vehicle-Miles Traveled (VMT). A key measure of overall street and highway use. Reducing VMT is often a major objective in efforts to reduce vehicular congestion and achieve regional air quality goals.

View Corridor. The line of sight 1) identified as to height, width, and distance 2) of an observer looking toward an object of significance to the community (e.g., ridgeline, river, historic building, etc.); the route that directs the viewer's attention.

Viewshed. The area within view from a defined observation point.

Volume-to-Capacity Ratio. A measure of the operating capacity of a roadway or intersection, in terms of the number of vehicles passing through, divided by the number of vehicles that theoretically could pass through when the roadway or intersection is operating at its designed capacity. Abbreviated as "V/C". At a V/C ratio of 1.0, the roadway or intersection is operating at capacity. If the ratio is less than 1.0, the traffic facility has additional capacity. Although ratios slightly greater than 1.0 are possible, it is more likely that the peak hour will elongate into a "peak period." (See "Level of Service")

Waste. Sewage and any and all other waste substance, liquid, solid, gaseous, or radioactive, associated with human habitation, or of human or animal origin, or from any producing, manufacturing, or processing operation of whatever nature, including such wastes placed within containers of whatever nature, prior to and for the purpose of disposal.

Wastewater. Commonly known as sewage, consists of three categories of liquid wastes: 1) those conducted away from all except industrial uses – known as sanitary, or domestic sewage; 2) those produced by industrial processes – known as industrial sewage; and 3) surface water, groundwater and stormwater that flow directly into or infiltrate sewers – known as storm sewage.

Water Distribution System. A means of transporting water to its diverse consumers throughout a community. The system generally consists of transmission mains, lateral mains, pipes that serve individual buildings, fire hydrants and distribution reservoirs.

Water-efficient Landscaping. Landscaping designed to minimize water use and maximize energy efficiency.

Watercourse. Natural or once natural flowing (perennially or intermittently) water including rivers, streams and creeks. Includes natural waterways that have been channelized, but does not include manmade channels, ditches, and underground drainage and sewage systems.

Water Master Plan. An important tool in the development of an effective and efficient water system. Serves as a guide for the orderly reinforcement and future expansion of a water district's water system.

Water Recycling. The treatment and disinfection of municipal wastewater to provide a water supply suitable for non-potable or potable reuse.

Watershed. The total area above a given point on a watercourse that contributes water to its flow; the entire region drained by a waterway or watercourse that drains into a lake, or reservoir.

Water Supply System. A utility system designed to carry water from a source to its diverse consumers. The system often consists of one or more water sources, a means of transporting water from the source to a water treatment plant, the plant itself and a distribution system for transporting water to individual consumers.

Waterway. See "Watercourse"

Wetlands. Lands, including vernal pools, having one or more of the following attributes are wetlands: (1) at least periodically, the land supports a predominance of hydrophytes (plants whose habitat is water or very wet places); (2) the substratum is predominantly undrained hydric soil; or (3) it is an ephemeral or perennial stream and substratum is predominantly non-soil in which waters from a tributary drainage area of 100 acres or larger flow.

Wildland/Urban Interface. The geographical meeting point of two diverse systems: wildland and structures. At this interface, structures and vegetation are sufficiently close that a wildland fire could spread to structures or a structure fire could ignite vegetation.

Williamson Act. Known formally as the California Land Conservation Act of 1965, it was designed as an incentive to retain prime agricultural land and open space in agricultural use, thereby slowing its conversion to urban and suburban development. The program entails a 10-year contract between the city or county and an owner of land whereby the land is taxed on the basis of its agricultural use rather than the market value. The land becomes subject to certain enforceable restrictions, and certain conditions need to be met prior to approval of an agreement.

Zoning: The division of a city or county by legislative regulations into areas, or zones, that specify allowable uses for real property and size restrictions for buildings within these areas; a program that implements policies of the General Plan.

Zoning District: A designated section of a city or county for which prescribed land use requirements and building and development standards are uniform.
